† Data analysed by a two-way fixed effects analysis of variance of unweighted means for unequal group sizes.

‡ A learning criterion of 10 consecutive correct responses was used.

proliferation within this discrete population was determined subsequently by the incorporation of ³H-TdR into brain DNA, and the validity of the procedure was assessed by fine-resolution autoradiographic localisation. On the seventh day after birth the brains of half the offspring in each litter were examined. DNA⁴ was extracted from each brain and its radioactivity was determined. Autoradiograms were prepared from one animal in each litter.

The remaining offspring were examined for learning ability at maturity. On day 90 they were placed on a 23 h food deprivation schedule and tested for performance on a series of conditional discrimination tasks of increasing order of difficulty (Fig. 2). Animals were killed on day 300, blood collected and plasma concentrations of thyroxine⁵, testosterone⁶, insulin⁷ and corticosterone⁸ in response to stress measured to determine any hormonal changes which may have influenced behaviour.

Table 1 shows that growth hormone produced a significant increase in brain weight and cellular content. The number of cortical neurones increased as measured by the incorporation of ³H-TdR and subsequent localisation by autoradiography. In all autoradiograms a band of heavily labelled cells was found only in the supragranular layers of the cortex, indicating that ³H-TdR uptake specifically reflects the proliferation of neurones within this region. When examined for functional capacity, offspring of mothers treated with growth hormone during pregnancy showed enhanced ability, obtaining criterion performance in significantly fewer trials than controls. This difference became particularly apparent on the second two-cue learning task, where after 100 free trials, 63% of control animals had failed to reach criterion performance. In comparison, only one animal treated with growth hormone was unsuccessful by this time. Enhanced performance could not be attributed to activation changes as determined by both latency of responding and hormonal response to stress. No change was found in adult body weight or plasma hormone concentrations ($P > 0.05$). Indeed at maturity, brain structure and functional capacity seemed to be the sole consequences of growth hormone treatment.

These results show that the administration of growth hormone during the time of neuronal proliferation produces a permanent increase in the number of cortical neurones and that there is a subsequent enhancement of learning ability. Although this period has been largely neglected as a vulnerable period of brain development, these findings demonstrate that it is critical not only for growth but for subsequent intellectual capacity.

Depolarisation of *Onchidium* neurone by glycine

INTRACELLULAR recording of cholinergic synapses in the *Onchidium* oesophageal ganglia revealed one neurone, V-3, in the visceral ganglion in which neither membrane potential nor conductance changes after perfusion with 0.5 mM acetylcholine. Significant depolarisation with increased membrane conductance was caused by 1.3 mM glycine. This response to glycine is opposite to that of the mammalian spinal motoneurone¹⁻³. Neurones examined in the ganglia, except V-3, were not affected by glycine. Here we report the ionic mechanism of glycine depolarisation, and compare the effect of strychnine on glycine depolarisation with its antagonistic action of mammalian glycine inhibition⁴.

The excised oesophageal ganglia were continuously perfused with artificial seawater (NaCl 457.6 mM, KCl 9.6 mM, CaCl₂ 10.4 mM, MgCl₂ 48.5 mM, pH, 7.8 by Tris-HCl, at 23° C). Two microelectrodes were inserted into the V-3 neurone, one for recording the membrane potential, the other for applying current to polarise the membrane. The resting membrane potential was -56.3 ± 4.9 mV (mean ± s.d.) (30 cells). Some spontaneous excitatory postsynaptic potentials, but no spontaneous firings were observed. The cells were depolarised about 40 mV with the membrane conductance increased to about twice normal and they fired vigorously when 13 mM glycine was added to the perfusing solution. Ouabain (3×10^{-4} M) had no effect on the level of resting potential or glycine depolarisation. Thus, the depolarisation is probably not caused by the inactivation of an electrogenic Na pump⁵ or the activation of the outward Cl pump⁶. The glycine depolarisation did not change significantly when the chloride ions in the bathing solution were replaced by

Fig. 1 Effect of displacement of membrane potential on amplitude of glycine depolarisation (glycine, 13 mM). *b*, Glycine depolarisation at original resting potential (-53 mV); *a*, at depolarised membrane potential of 43 mV; *c*, at hyperpolarised membrane potential of 50 mV; *d*, Amplitude of glycine depolarisation plotted against three different levels of membrane potential. The membrane potential at the point where the dotted line crosses the abscissa was taken as the equilibrium potential for glycine depolarisation. RP, original resting membrane potential (-53 mV). NSW, normal seawater.

Fig. 2 Relationship between amplitude of glycine (13 mM) depolarisation and $[Na]_o$ in seawater. Amplitude of glycine depolarisation (mean \pm s.d., three V-3 neurones) plotted against $[Na]_o$. Average of original resting membrane potential is shown as RP. The resting potential was stepwise hyperpolarised a total of approximately 17 mV by stepwise decrease from 1 to 1/50 in $[Na]_o$. Thus each glycine depolarisation was the shift from the new resting potential at each new $[Na]_o$ concentration.

acetate. Increase of $[K]_o$ to twice normal did not change glycine depolarisation.

To determine the equilibrium potential for glycine depolarisation, the membrane potential was changed by current application. Figure 1 shows an equilibrium potential of +30 mV obtained by extrapolation of three experimental values. This high potential indicates that the ions involved in the generation of glycine depolarisation are probably Na, or Ca ions, or both.

The next series of experiments therefore consisted in changing $[Na]_o$ to modify this concentration gradient across the cell membrane (NaCl replaced by Tris-Cl). Stepwise decrease in $[Na]_o$ from 457.6 to 9.1 mM caused a corresponding stepwise decrease in the level of depolarisation by 13 mM glycine (Fig. 2). Note that the normal resting potential was hyperpolarised in steps corresponding to the stepwise decrease in $[Na]_o$ from 1 to 1/50. The total amount of hyperpolarisation was approximately 17 mV. The reported depolarisation values are those measured from each respective new 'resting potential'. The change in depolarisation for 10 times change in $[Na]_o$ was about 30 mV. Tetrodotoxin (3×10^{-5} M) had no effect on glycine depolarisation. This indicates that the glycine effect is probably taking place at the subsynaptic membrane⁷⁻⁸. For a five-fold increase of $[Ca]_o$, the glycine depolarisation remained at the same level. Hence, it may be concluded that glycine depolarisation is due exclusively to an increased permeability of the membrane to Na. Doubling the concentration of Mg (97 mM) in seawater had no effect on the glycine depolarisation. The lack of effect of Mg as well as Ca indicates that the glycine action is subsynaptic rather than presynaptic. Glycine was also effective when applied locally to the soma and neck of the V-3 neurone by passive diffusion from a glass microelectrode (tip diameter, about 3 μ m). The neck portion of this neurone was much more sensitive to glycine than was the soma. Synapses of the *Onchidium* nervous system are always axo-axonic and are located in the neuropile at various distances from the soma (T. Yamamoto, unpublished observation).

Interestingly, the effect of glycine on the V-3 neurone was augmented, not blocked, by 2.5×10^{-4} M strychnine. Figure 3a shows depolarisations at various concentrations of glycine from 0.1 to 130 mM; Fig. 3b shows the augmenting effect of strychnine on each glycine depolarisation. The membrane conductance at the plateau phase of depolarisation by glycine plus strychnine (Fig. 3b, right) was certainly no larger than that from glycine alone (Fig. 3a, right). It may even have been smaller. Strychnine alone in this concentration had no detectable effect on the resting

Fig. 3 Augmenting effect of strychnine on glycine depolarisation at various concentrations of glycine. *a*, Glycine alone; *b*, glycine (0.1 to 130 mM) plus 2.5×10^{-4} M strychnine. Figures indicate glycine concentration (mM). Strychnine alone had no effect on the resting membrane potential or conductance.

membrane property, in contrast to its effect on the giant axon of the lobster⁹. The equilibrium potential of glycine depolarisation was 22.7 ± 2.7 mV (four cells); that of glycine plus strychnine was 41.4 ± 3.2 mV. The increase in membrane conductance was $58.3 \pm 16.2\%$ in the former and $44.7 \pm 5.1\%$ in the latter. The differences in equilibrium potential and membrane conductance change for glycine plus strychnine compared with glycine alone indicate that the strychnine augmentation is caused by a decrease in K permeability.

Mention of the effect of GABA on the V-3 neurone may be worthwhile. α -Amino butyric acid (GABA, 10 mM) caused a few mV depolarisations of the V-3 neurone. At the same time it caused a decrease in membrane conductance to about 80% of normal. Preliminary experiments indicate that this depolarisation results in a decrease of the resting K permeability of the subsynaptic membrane. This effect is completely different from that on the vertebrate pre and postsynaptic membranes. Both membranes are depolarised by GABA due to increased Na and Cl permeability respectively¹⁰⁻¹².

In summary, glycine is excitatory in the V-3 neurone. Glycine depolarisation is due solely to increase in Na permeability at the subsynaptic membrane. Strychnine augmentation is caused by K permeability decrease during the glycine depolarisation. The effects of glycine and GABA on the membrane properties of *Onchidium* are very different from their effects on vertebrate neurones.

Leptospiral motility

THE motility of spirochaetes, especially the *Leptospira*, has interested many workers but has remained unexplained despite the application of modern techniques. Inadequate observations by Noguchi¹ have been used by modern workers (Ritchie and Ellinghausen²; Nauman³) to construct inaccurate models of leptospiral movement, the main inaccuracy of which is that leptospirae rotate upon their axes in free liquid. Noguchi¹, however, did observe that "when

one end is straight and the other semicircularly hooked, the organism usually progresses in the direction of the straight portion and seems to be propelled from the rear by the rotating hook". Although not correct in important details, the observation of translational movement in the direction of a straightened portion is a fundamental principle. Previous observations and explanations were at variance with the physical principles of fluid mechanics. This paper presents information which we believe to be in accord with such principles.

Observations were made using a Reichert Zetopan microscope set for dark ground operation. Videorecordings were made to aid the categorising of the movements, and direct observation was used to analyse the finer details. The organism used was *Leptospira icterohaemorrhagiae* strain 3H cultured in Korthof medium. Particulate matter was supplied to the organism either as particles of agar added to the culture on the microscope slide, or by allowing an active culture to invade semi-solid nutrient agar.

Movement in free liquid. With non-translational movement (Fig. 1a) the body remains relatively stationary with

Fig. 1 Motility of *Leptospira icterohaemorrhagiae*. a, Non-translational movement in free liquid; b, translational movement in free liquid; c, crawling on a smooth surface; d, anchoring on a smooth surface; e, staple movement on a smooth surface. Arrows indicate point of fixation.

either end waving in a circular motion in opposite directions. The rapid movement gives the appearance of spinning and the hooked ends blur into the familiar 'button hole' figure. Illumination causes the organisms to move more slowly and under such conditions contra-rotation of the hooked ends may be observed. Though care must be exercised in extrapolating from the behaviour of such organisms to the normal state, the observation that organisms decelerate smoothly would suggest that an abrupt change is unlikely. The forces produced by this type of movement are seen to be equal in all directions as there is no net change in the position of the organism.

When movement is Translational (Fig. 1b), the end towards which the translation is effected performs helical waves travelling for a short distance of the length of the cell towards the trailing end. The trailing end forms a broad hook which waves in an irregular circle in the opposite direction to the propulsive helical wave to provide stability and prevent rotation of the whole body. The helical wave may also be observed when a portion of the body is fixed to or embedded in a particle and unable to rotate. An organism has been observed moving with a piece of colloidal graphite fixed to the tip of the trailing end. The particle was so massive with respect to the organism that there was no tendency for the body to rotate, emphasising the function of the hooked tail.

Movement on a smooth substrate. *Leptospira* may crawl (Fig. 1c) either like a snake or, alternatively, by lifting clear and then reapplying parts of the body. A variant on this is circular crawling in which no sideways waves of propulsion are seen. The body in this case follows a circular path, the circumference of which is normally less than the length of the body.

The organism may be anchored (Fig. 1d). One end may remain fixed to the substrate despite high rates of flow in the medium. Frequently one end of the organism is seen to be fixed to itself further along, in place of the substrate.

A third possibility is *staple movement* (Fig. 1e) so called because it can be imagined that the organism is passing through a staple or hoop fixed to the substrate. This movement often follows anchoring and is most probably due to the same process. By virtue of the small radius of the protoplasmic cylinder the surface energy would be relatively high, providing the physical adhesion necessary for this type of behaviour. When the organism moves through the 'staple' the spiral of the protoplasmic cylinder behaves as if it were a screw, threading through a small hole. This keeps the cell in intimate contact with the substrate in accordance with the surface energy concept. There is at present no direct evidence to indicate that surface energy forces are responsible for the phenomena observed. Equally, there is no evidence to indicate the presence of adhesive organelles or the secretion of adhesive substances.

Movements in semi-solid medium. Translation is effected by snaking through the medium with the body conforming to the texture of the medium. The body is very flexible. It is not obvious how movement is actually carried out but the body once again screws through the medium.

The most important point to arise from these observations is the notion that when moving in free liquid *Leptospira* do not rotate about the axis as has previously been supposed. The hook at the trailing end of an organism performing translational movement remains relatively still thereby providing an 'inert head' fundamental to the effectiveness of the helical waves of the leading end of the cell as demanded by Taylor's calculations on propulsion by helical waves¹. This basic requirement is not included in previous observations.

A certain amount of roll about the long axis is inevitable as a consequence of the helical nature of the propulsive waves², but this can be seen to be corrected for by flicking movements of the trailing hook. Any remaining rotation could not be confused with the rapid spinning described previously¹⁻³.

The rapid spinning seen in nontranslatory movement is now seen to be an illusion. There is no process available to produce rapid spinning in the absence of flagellae, cilia or jet devices, none of which have been observed. It is, however, a physical reality that the ends can wave in circles of opposite direction, each providing the necessary reaction to the other.

Any attempts to explain these movements at the sub-cellular level must be speculative at the moment. It is possible that the axial filaments might be responsible, provided that they extend along the axis of the body as a whole and are not themselves spiralled structures. This condition seems to be fulfilled³, a fact which eases the problem somewhat, since a system whereby a spiralled filament produces secondary spiral waves defies imagination. The axial filaments are known to extend from each end of the cell for a short distance towards the middle, and it is the terminal portion of the cell that performs the locomotory function.

The importance of these observations to the study of leptospirae as pathogens lies in the insight gained as to how the pathogen solves some of the problems posed by both the external environment and the internal environ-

ment of the body of the host.

We thank the Agricultural Research Council for a grant to purchase the Reichert Zeptopan Microscope.

Bioassay of a *Drosophila* pheromone influencing sexual selection

PHEROMONES function by transmitting information from a sending to a receiving organism by chemical means. In a classic paper, Bossert and Wilson classified the effects of such information transfer into releasing and priming¹. Releaser pheromones evoke an immediate overt behavioural effect, whereas primer pheromones activate the chemoreceptor in such a way as to alter the physiology of the receiving organism^{1,2}. In general, studies involving the isolation identification of pheromones have concentrated on releasers such as sex attractants, alarm pheromones, trail pheromones and aggregation pheromones³. The advantage of using releaser pheromones in such studies is that the behavioural effects can be observed even in a single individual of the appropriate age, sex and species. This makes the development of a relatively simple and rapid bioassay a straightforward process. So far the important exception to the use of releaser pheromones has been the work of Butler *et al.* showing that 9-ketodecenoic acid inhibits ovarian development in worker bees⁴. This substance, however, was first identified as the sex attractant of the queen bee and later shown to have a primer effect. We describe here a bioassay for a substance with an effect which does not fit easily into either the releaser or primer category.

We have been attempting to isolate and identify the pheromones responsible for the rare male behaviour found in *Drosophila* of several species and in other organisms⁵⁻⁷. Rare male behaviour is characterised by females preferring the strain of males in least abundance presented to them as potential mates. This rare male advantage may have evolutionary significance, since it provides a mechanism for preserving a heterogeneous gene pool.

In particular we are concerned with two intensively studied strains of *Drosophila pseudoobscura*, homozygous Chiricahua (CH) and homozygous Arrowhead (AR) — differing in third chromosome inversions⁸. Previous work has shown that when the ratio of males (CH:AR) is sufficiently different from 1.0, males of the strain in least abundance are favoured as mates by females of both strains (Fig. 1)^{6,7}. Furthermore, a compound or compounds of low polarity extractable from CH males into light petroleum ether (and to a much lesser extent into acetone) has been

shown to be capable of producing an advantage for AR males when the AR:CH ratio is 1.0 (ref. 7).

Attempting to isolate and identify this active material, we have been led to quantify the assay, and in doing so have been able to show that the behaviour can be controlled substantially by olfactory cues alone. In the mating trials, any extract was spotted on to the filter paper bottom of an Elens-Wattiaux observation chamber⁸ and the solvent allowed to evaporate. Twelve aged females from each of the two strains were then introduced unanaesthetised and allowed to acclimate to the chamber for 1 min. Eighteen AR males and six CH males were then introduced in a similar manner and all matings were scored by direct observation with a hand lens. As Fig. 1 shows, this CH:AR ratio of 0.33 normally produced nonrandom mating frequencies favouring the rare CH males; this held true both in clean chambers and in the presence of inactive compounds, solvent or low concentrations of active material. In the presence of petroleum ether extracts of CH males, however (prepared by tissue grinding flies in acetone, centrifuging, decanting and extracting the pellet with petroleum ether, 30°–60° C), this rare male advantage could be removed. As Fig. 2 shows, this removal exhibited a threshold above which random mating (as measured by χ^2) is observed. The relatively high value of this threshold (ten to fifteen flies extracted per fly present) may indicate that the extraction was incomplete or resulted in degradation or loss of the material, that the actual pheromone release was directional (and hence more sparing of material), and/or that other cues (such as auditory, visual or tactile sensations^{9–11}) supplement the olfactory signals. The persistence of random matings even to high multiples of the threshold value lends strength to the supposition that other cues are also important.

This bioassay, and hence the behaviour which it measures, differs significantly from procedures generally used. Unlike the usual assays of releaser pheromones, our bioassay cannot be conducted with individual organisms. The pheromone appears to bias the female's response in a predictable manner, but in a way which cannot be measured for individual females. Furthermore, unlike the situation with primer pheromones, the effect is observable on a very short time scale. In a different context from the reports

Fig. 1 As the AR:CH ratio approached 50:50, the mating advantage of the CH males disappeared. Ratios are based on a total of 96 observed matings. To guarantee the vitality of the stocks, only chambers in which all females mated are included.

mentioned above, E. O. Wilson has spoken of the "intractable" recognition substances which are "deserving targets for the best efforts of chemists in the future"¹². The females of the *D. pseudoobscura* strains studied are clearly using a chemical cue to determine the presence of males of the CH strain, and altering their behaviour accordingly. Rather than releasing an overt behavioural effect or altering the female's physiology in a long term manner, the

Fig. 2 As further petroleum ether extract of CH males were added to the chambers, the mating advantage of CH males disappeared. Ratios are based on 48 observed matings in chambers where all females mated. The assay can also be run using a 50:50 AR:CH ratio; a full advantage for AR (as determined by the χ^2 for randomness) can be achieved. This assay is used because it appears to provide a better internal control for the vitality of the critical CH flies. There is no significant difference in the statistical stringency of the two assays.

olfactory cue seems to act as information, pure and simple. Although other information (auditory, visual, tactile) is also utilised, the olfactory cue can strongly bias whatever mechanism operates in the females to determine their choice of mates. This work was supported by a US Public Health Service National Institutes of Health research grant.

Dietary preference and diseases of age

THE frequency of a number of tumour types and several age-related diseases are readily modified by dietary means¹⁻⁸. Traditionally, in defining the influence of a dietary factor experimentally, diets of fixed composition are offered either *ad libitum* or in limited amounts for arbitrarily assigned periods. In *ad libitum* conditions, however, except for the amount of food consumed, the animals have no choice but to eat the diet provided; in restricted feeding conditions, even this option is denied them.

The element of dietary preference was introduced in the investigations reported here. This new approach to long term studies was suggested by the well-established fact that the young rat, unless it has been biased by previous experience or training, has the ability to select for itself essential dietary substances in amounts necessary to sustain life, to grow and to reproduce⁹⁻¹². That this behaviour represents a response to specific metabolic 'needs' is supported by the observations that a variety of conditions which alter metabolism generally results in compensatory changes in appetite for specific food substances¹³⁻²².

The self-selection (S-S) method of feeding seems to have several advantages over a 'fixed' dietary regimen: the diet selected is of physiological significance to the individual, at least during the growth period of life; it more closely approximates the natural condition; and the arbitrary decisions made by the investigator as to the quality of the diet without considering the needs of the individual are avoided. In addition, by permitting the animals to display their preferences, it may be possible to assess on an individual basis the long term consequences of dietary habits at different stages of life.

In this study we provided each rat fed on the S-S basis, three complete isocaloric diets⁸ in separate containers instead of the individual components. They differed only in their casein and sucrose content. To determine the influence of each of the diets separately, other rats were fed *ad libitum* in the conventional manner.

The regimen of the individually housed male Charles River COBS rats, which genetically are relatively heterogeneous, was begun when they were 21 d of age and was maintained for the remainder of the animals' lives (the age at death of the longest lived rat was 1,075 d). The amount of each of the diets consumed by each S-S rat was determined daily. The dietary history during the gestation and suckling periods has been described^{8,23}. Upon the death of each rat, a thorough necropsy was performed and samples of all normal and diseased tissues were taken for histopathological examination. The tissue sections were coded so as to preclude identification with the age and dietary history of the animal.

Far more 'spontaneous' tumours and more cases of kidney, heart, and prostate gland disease occurred among the S-S rats than among the rats fed the same diets singly (Table 1). Indeed, there were a number of tumours for which the incidence among the S-S rats was as great or greater than among all three conventionally fed groups combined. These included benign tumours without respect to type, adenomas and carcinomas without respect to site, leukaemia, tumours of the anterior pituitary, adrenal, exocrine pancreas, and skin. This also held for advanced cases of glomerulonephrosis, myocardial fibrosis, and for prostatitis. Adjustments for time of occurrence, age-specific morbidity rates, population size and length of life, confirmed the differences in risk (Table 1). In addition to the significantly higher incidences, more S-S rats had multiple affections at time of death than did those on the fixed diets; 66% of the S-S rats had at least three of these diseases as compared with 9, 26, and 28% for rats fed low, intermediate, and high protein diets (D₁₀, D₂₂ and D₅₁), respectively.

The higher incidences of the S-S rats were not attributable to longer life spans. Although the S-S rats had a higher life expectancy than rats on the fixed diets, this was limited to age periods before 400 d. Once the various diseases manifested themselves, the life expectancy of the S-S rats was lower than

those of the other groups. The change to higher age-specific mortality rates was commensurate with the consistently higher age-specific morbidity rates.

With the conventional feeding method, the frequencies of the non-neoplastic diseases (Table 1), and of several tumour types⁸, were dependent upon the proportion of protein in the diet.

*Diets identified according to the proportion of the casein component.

†Average casein content of the composite diet selected throughout the greater part of life, between 27-28%.

‡Number of rats: 125 in the S-S group, 250 in each group provided one diet only.

§P, < 10⁻³. ¶P, < 0.01; disease frequency for D₅₁ significantly different from D₁₀. Absence of superscript indicates difference between groups, N. S. Fisher's exact probability test applied to empirical data. χ² test of association among the 3 groups significant for all grades and for moderate and severe cases of glomerulonephrosis and myocardial fibrosis (P, < 10⁻³; < 10⁻⁶; < 10⁻⁶; < 10⁻⁴, respectively).

**P, < 10⁻⁶; **P, < 0.003; S-S frequency significantly higher than that of the fixed dietary group with the highest frequency.

††Relative morbidity ratio (x 100), all ages. Values of 100 assigned to the fixed dietary group with the highest frequency. Values in the S-S group > 100 indicate extent of increase in risk relative to that of the fixed dietary group. Morbidity ratio = c_x / \bar{c}_x , where c_x = number of cases observed in the S-S group and \bar{c}_x = expected number of cases: $\bar{c}_x = (\bar{c}_{x1} \times l_{x1}) + (\bar{c}_{x2} \times l_{x2}) + \bar{c}_{x3} \times l_{x3}$, . . . where $\bar{c}_{x1,2,3, \dots}$ = 'standard' age-specific morbidity rates, consecutive 100 d periods and $l_{x1,2,3, \dots}$ = exposure (that is, number of living S-S rats entering an age period) consecutive 100 d periods. For each disease class, age-specific morbidity rates of the fixed dietary group with the highest frequency used as standard rates.

The increase in the prevalence of these diseases for the S-S rats cannot be explained on this basis as the protein/carbohydrate ratio of the diet selected by any of the S-S rats had to fall within the upper and lower limits of the three fixed diets.

The S-S rats grew more rapidly and attained higher body weights than rats fed the diets separately. We had shown^{23,24} that among conventionally fed rats those which grew more rapidly and attained higher body weights during maturity had a higher risk of tumours than those with lower rates of growth and lower maximum body weights. Body weight differences, however, do not explain the marked increase in disease proneness of the S-S rats. For this analysis, each of the S-S rats was weight-paired with individuals from the D₂₂ group. There was,

consistently, a greater number of tumour bearing rats in the S-S group than among conventionally fed rats. For example, on the basis of the body weight at 98 d old, 60% of the S-S rats but only 23% of rats of corresponding body weights from the D₂₂ group subsequently developed tumours. When maximum body weights were matched, 58 and 33% of the rats maintained on the S-S and D₂₂ regimens, respectively, developed tumours.

No two S-S rats exhibited the same dietary preferences. After an initial rapid increase in the amount of food consumed, the daily intake by each rat remained relatively uniform from 11 to as much as 49 weeks. By 1 y of age, 90% of the rats showed a

Table 2 Dietary preference and disease frequency

*†Rats classed according to dietary choice during 200–300 d of age.

†Number of rats in each subclass was 40 or 41 (4 rats died before 100 d).

‡Class limits: low = 12.0–24.8%; intermediate = 25.2–30.3%; high = 30.4–43.0%.

§Class limits: low = 16.1–20.2 g; intermediate = 20.3–21.9 g; high = 22.0–26.8 g.

¶Among rats maintained on fixed diets, the highest frequency was: all epithelial tumours, 27%; adenomas, 20%; all endocrine tumours, 20%; anterior pituitary tumours, 10%; pancreatic tumours, 6%. Additional values given in Table 1.

"All grades of severity.

**Frequency of epithelial tumours of the intermediate dietary subclass significantly higher than that of the high-protein subclass ($P < 0.02$). Absence of superscript indicates no significant difference between subclasses. (Fisher's exact probability test applied to empirical data). χ^2 test of association among the three subclasses also not significant.

marked and progressive increase in food intake. Before death, only a few animals failed to decrease their intake of food. The level of intake during each of these phases differed widely from rat to rat.

Within the first 5 weeks of feeding, most of the rats established the level of protein and carbohydrate that each would continue to select for a prolonged period. Despite variation in relative preference for the three diets or in the amount of food consumed, the protein: carbohydrate ratio of the resulting composite diet was maintained by some rats for as long as 700 d.

The associations between disease susceptibility and dietary preferences were evaluated by separate rankings of the S-S rats according to the protein content of the composite diet selected and the amount of food consumed. The tumour data are limited to several tumour types, as the numerous tumour classifications that should be made cannot be adequately treated in a short communication.

The data shown in Table 2 for the S-S rats are, in general, representative of the relationships seen at earlier and successive 100 d age periods until 600 d of age was attained. Beyond this time, the progressive decrease in number of animals precluded

further analyses; that is, of the number of rats started in the experiment, 45 and 75% had died by 600 and 700 d, respectively.

The prevalence of the four diseases among the S-S rats, classed according to the protein content of the diet, was almost without exception greater at any level of protein than those of rats maintained on any of the fixed regimens. In addition, whereas the incidences of the renal, myocardial, and prostate gland diseases for the rats on the fixed diets (Table 1) are strongly dependent on the proportion of the protein component of the diet, among the S-S rats the protein dependencies were weak or nonexistent (Table 2). Irrespective of the protein content of the diet the frequency of several types of tumours tended to increase slightly among animals whose food intake was higher. The mean length of life, however, tended to decrease 690 ± 124 , 622 ± 123 , and 580 ± 104 d, respectively). Even so, the differences in the incidences for the neoplastic and non-neoplastic diseases among the subgroups were not significant. In contrast, with fixed regimens the trends for most tumours were consistently striking and statistically significant²⁴.

Unless the members of an experimental population are highly inbred or subjected to extraordinary environmental experiences, not all of the individuals will develop any of the common age-related diseases. In conventional *ad libitum* feeding practices, changes in the prevalence and severity of the observed idiopathic diseases could be taken to represent a dose-response relationship. In S-S conditions, the diet chosen differs from animal to animal and yet equivalent or nearly equivalent effects are exerted by any one diet on disease susceptibility. The dose-response interpretation cannot be applied to the free choice situation. Rather, the impressive increase in the risk of developing tumours or of other diseases of age must be viewed as the direct consequence of the specific selections made by the individual in satisfying its unique metabolic 'needs'.

Evidence for the inhibition hypothesis in expanded angle illusion

THE illusory expansion of acute angles has long been suspected to be an important contributory factor in a number of well known illusions, such as the Zollner, the Wundt-Hering and the Poggendorf^{1,2}. Recently Blakemore, Carpenter and Georgeson³ proposed that angle expansion is a side effect of an inhibitory process that improves the orientation resolution of the visual system. Neural line and edge detectors considered in isolation, are assumed to respond to a wide range of orientations, but when incorporated into a functional system inhibitory interactions occur between them which sharpen the specification of a line or edge⁴. When two spatially contiguous lines of neighbouring orientations are exposed simultaneously, however, the activity peaks in the population of orientation detectors are shifted away from each other because of the inhibitory interactions. Consequently, the orientations of the lines comprising the angle are perceived wrongly. This process of central lateral inhibition is thought to be similar to that which operates in peripheral sensory structures⁵. It seems natural to ask how far this similarity extends.

Hartline and associates⁶ have described the following major features of inhibition in the compound eye of *Limulus*⁶. First, the distance effect—as the test and inducing stimuli are moved further apart the effectiveness of the inhibition decreases. In the orientation domain experimental evidence indicates that following an initial rapid build up, the illusion diminishes as the angular separation increases^{3,7}. Second, the area effect—the larger the number of neighbouring facets illuminated, the greater the inhibition of the test ommatidium. Extrapolated to the visual cortex, one might expect the induced change in orientation of a test line will be proportional to the number of parallel lines of neighbouring orientation exposed in its vicinity. Experimental data provided by Ogasawara⁸ and Wallace and Crampin⁹ show the larger the number of parallel lines that cross a contour, the greater its angular distortion. If the inducing lines are not parallel then inhibitory interactions will occur between them thus ‘disinhibiting’ their potential combined action on the test line. Evidence that disinhibition does occur in the case of interactions between orientations has been provided by Carpenter and Blakemore⁷. Third, the intensity effect—for a given distance between inducing and test omma-

tidia, the more intense the illumination falling on the inducing facet the more intense the inhibition of the test ommatidium. Where two facets are unequally illuminated, the inhibitory interaction increases the differences in their outputs. Extrapolated to the case of interactions between orientations, these effects suggest the following predictions. If two lines of neighbouring orientations are unequally illuminated, then the angular distortion of the two lines will be unequal because proportionally more inhibition, and therefore more angular distortion, of the dimmer line by the brighter will occur than *vice versa*. Where the luminance of both lines is equal, little change would be expected in the magnitude of the mutual distortion as the absolute luminance is varied over a fairly wide range, as the inhibition should remain proportionately similar. Because verification of these predictions would constitute valuable support for the theory it was decided to test them specifically.

The subject, his chin supported by a rest, looked at the display through a 4 mm artificial pupil with his right eye. The display consisted of a pair of lines, each subtending $2.0^\circ \times 0.17^\circ$, forming an acute angle, whose luminance could be varied independently, or in unison, with neutral density filters. The illusion size was measured in the same way as that employed by Blakemore *et al.*³. A small comparison line, subtending $1.2^\circ \times 0.1^\circ$, was positioned 2.0° from the base line (*B*) of the angle (Fig. 1) by means of a half-silvered mirror. By moving a lever, which rotated a Dove prism, the orientation of the comparison line was adjusted to appear parallel to *B*. The maximum luminance of the angle lines was 8.5 cd m^{-2} and the comparison line was constant at 2.0 cd m^{-2} . Before each estimate of the orientation of *B*, the comparison line was offset $30\text{--}40^\circ$. The subject placed his head on the rest and the room lighting was turned off. The subject adjusted the comparison line, usually in 5–6 s, then the room lighting was turned on and the reading

Fig. 1 The inset shows the arrangement of lines used in the present study. *A*, angle line; *B*, base line; *C*, comparison line. Angle of *A* and *B* = 15° . ●—●, *A* constant, luminance of *B* decreased. ○—○, Luminance of *A* and *B* decreased concomitantly. ○—○, *B* constant, luminance of *A* decreased. In all cases illusion magnitude was calculated as orientation of *B* in absence of *A* minus orientation of *B* in presence of *A*.

noted. Each of five subjects made seven estimates of the orientation of *B* under each luminance condition for the three experiments (15 subjects in all). The order in which the estimates were made was changed for each subject.

The results presented in Fig. 1 are for the case where the orientation of *B* with respect to the vertical was 5° anticlockwise, and *A* was positioned 10° clockwise. The upper curve in Fig. 1 shows the progressive increase in the induced tilt of line *B* as it is made dimmer than *A*, indicative of a greater inhibitory effect of *A* on *B*. Analysis of variance on the data showed that this change was significant ($P < 0.01$). The lower curve in Fig. 1 plots the significant reduction ($P < 0.01$) in the induced tilt effect as the luminance of *B* is held constant and that of *A* reduced, indicative of a reduced effect of *A* on *B* as *A* becomes dimmer. The middle curve shows the nonsignificant change in illusion size ($F = 0.735$, d.f. = 2, 8), as the brightness of both *A* and *B* was varied concomitantly over two log units. These results show that the size of the induced tilt effect varies systematically as a function of the relative, but not the absolute luminance of the test and inducing lines. The effect is not confined to this particular orientation of *A* and *B*, nor is it a function of the particular angle used here (15°). The effect is also obtainable when a subjective vertical criterion is used to estimate the orientation of *B*, so the results cannot be due to any interaction with the comparison line.

It is known that the relative luminance of spatially adjacent areas affects their perceived brightness¹⁰. These results show that the relative luminance of orientationally adjacent contours affects their perceived orientation and offer evidence in favour of the hypothesis that angle expansion is the result of an inhibitory process. While the results are similar to a relative contrast phenomenon recently demonstrated for the tilt after effect (TAE)¹¹, the explanation of the present results in terms of adaptation must be rejected for other reasons. The angle expansion illusion is known to be spatial frequency specific¹² while the TAE is not^{11,13}. The TAE also shows an 'indirect effect' when the adapting stimulus is in the region of 90° from the test stimulus¹³, which is not true of the illusion.

The similarities in the operation of inhibition processes in simple visual systems and the interactions between lines indicate that lateral inhibition may be a more general phenomenon than is commonly realised and suggests that certain illusions which involve neighbouring orientations may be explained without the theoretical involvement of constancy mechanisms¹⁴.

Form-specific colour after effects in scotopic illumination

THE retina of the human eye contains rod and cone receptors, and in very dim light the rods alone function (scotopic illumination) so that objects appear colourless. At higher light levels, cones also function (photopic illumination) and colours are seen.

There is evidence that rods interact only with rods and that the various colour mechanisms, the Stiles π mechanisms, act independently¹⁻⁵. These events probably occur early in the retina, for the various channels interact even within the retina⁶, and the later stages of the visual system show a strong opponent colour organisation. Other evidence suggests that rod and cone signals interact; in these studies colour sensations are elicited through rods. For example, if one first views a coloured flash that affects cones, a complementary coloured afterimage is seen upon viewing a dim flash that affects only rods⁷. The rods seem to trigger this after image⁸, for its hue remains constant as the wavelength of the dim test flash is varied, and the light level sufficient to trigger the after image coincides with the dark adaptation curve of the rods. Simultaneous contrast colours of blue and green are seen in a bipartite field when one half is illuminated with dim light, that stimulates only rods and the other half is illuminated with long wavelength light that stimulates cones⁹⁻¹⁰. Similarly, many colours are seen in a Land two-colour projection produced with two illuminants that stimulate differently long wavelength cones and rods¹¹. These studies suggest that rod and cone signals converge at some level of the visual system.

I have found that form-specific colour after effects—the McCollough effect—can be seen on test patterns observed in dim light that stimulates the rods but not the cones. This shows that rod signals feed into colour mechanisms. McCollough¹² discovered that after adapting for several minutes to a vertical grating in orange light alternating with a horizontal grating in blue light, black and white test gratings with retinal orientation similar to the adapting patterns were tinged with colours complementary to the adapting colours. For example, the vertical test grating appeared blue and the horizontal orange.

Fig. 1 Dark adaptation curve for one observer. The bars on the right indicate various luminance values for white bars of test patterns.

Fig. 2 Test pattern. Gratings had spatial frequency of 0.75 cycles per degree.

Of the three observers I used, two were highly experienced with the after effect and one was uninformed about the experiment. Dark adaptation curves were first measured on the two experienced observers. After strong light adaptation, the observer fixated a tiny red light in the centre of a 10° diameter disk of white paper on a black background and adjusted a neutral wedge, which controlled the illumination level, so that the disk remained just below threshold. These materials had the same reflectance as the test patterns used later. The light came from a regulated projector with accessory lenses and was filtered through a narrow-band yellow-green filter (Wratten 74, dom λ 538nm). The curve for one observer is shown in Fig. 1. The vertical axis represents the luminance of the white disk. The curve for the other observer was very similar. The level of the rod-cone break agrees with the value measured by Chapanis¹³ for a green spot 3° in diameter, 7° from the fovea, which was flashed on for 0.2 s. It was also noticed, subsequently, that the appearance of the test patterns (Figs. 2 and 3) changed markedly near the break: the bars of the gratings appeared sharp just above the break and diffuse just below the break. Rods alone presumably function below the break, for the break is generally assumed to indicate cone threshold.

Colour after effects were next built up with high-contrast square-wave gratings of 0.75 cycles per degree, rear-projected on a diffusing screen. Gratings subtended an area about 30° square. A tiny light was placed in the centre of the screen. Gratings were projected in alternate vertical and horizontal orientations and interchanged every second. On each presentation the gratings were projected in the same position or shifted 180° in phase by mirrors. The shift was determined randomly. The observer stared at the light to help adapt the eyes evenly. The observer adapted for 20 min to the alternating vertical grating in green light (Wratten 40 filter) and the horizontal grating in complementary magenta light (Wratten 31 filter). Mean luminance was about 70 m lamberts. The observer next dark adapted for 30 min and viewed the test pattern (Fig. 2) illuminated with the light used to measure the dark adaptation curves. The luminance of the white areas of the test gratings was set at values indicated by the bars in Fig. 1, starting at the lowest level and moving upward. The spatial frequency of the test pattern was the same as the adapting patterns, 0.75 cycles per degree. The pattern was about 48° square.

The vertical and horizontal gratings of the test pattern appeared faintly pinkish and greenish, respectively, to all observers at the lowest light level, -1.8 log units below the rod-cone break. The colour became more saturated

as the light was increased. The naive observer later matched from memory the strongest scotopic after effects to Munsell colour chips viewed in Macbeth daylight=6750 K. The colours chosen were 10 RP 7/8 and 10 GY 7/8. All observers claimed that the scotopic colours were quite saturated.

The McCollough effect is somewhat specific to the spatial frequency of the adapting pattern¹⁴. The present experiment demonstrates that the colour effect stays tied to the adapting frequency even for test patterns in scotopic light. The previous experiment was essentially repeated using two vertical adapting gratings of 0.5 and 2.0 cycles per degree. The observer again viewed the fixation light in the centre of the adapting field. The patterns were about 30° square and centred on the fixation light. The 0.5 cycles per degree pattern alone was projected in the same position or shifted 180° in phase, as before; the 2.0 cycles per degree pattern was always projected in the same position. Observers adapted for 40–60 min to one grating in green light, alternating with the second grating in magenta light. For some observers, the two gratings were shown for unequal amounts of time to build up good pink and green after-effects. (Low frequency grating were used, because below the rod-cone break gratings above 5 cycles per degree cannot be resolved¹⁵.) After colour adaptation, the test pattern (Fig. 3) was viewed in Macbeth daylight and then, after dark adaptation, in scotopic light at levels from -1.0 to -0.3 log units below the rod-cone break. The pattern was about 15° wide and 30° high. The test gratings appeared appropriately coloured. For example, adaptation to 0.5 and 2.0 cycles per degree gratings in magenta and green light, respectively, produced a green after effect on the 0.5 cycles per degree test grating and a pink after effect on the 2.0 cycles per degree grating. All observers claimed that the colours were more saturated at scotopic than photopic levels.

That the after effect stays tied to the adapting spatial frequency suggests that the receptive field of the mechanism underlying these effects does not lose its antagonistic surround at scotopic levels. Loss of the surround would cause pattern of low spatial frequency to elicit both the pink and green after effects, and no colour would be seen since the two colours are complementary and would thus cancel. Adaptation to luminance gratings at low mesopic levels has been shown to raise the threshold only for grat-

Fig. 3 Test pattern. The spatial frequencies of the test gratings were 0.5 cycles per degree (a) and 2 cycles per degree (b).

ings of similar spatial frequencies¹⁶. My results suggest that adaptation is frequency-selective at even lower scotopic levels. The existence of lateral inhibition at scotopic levels is further suggested by studies on simultaneous brightness contrast¹⁷, Mach bands¹⁸, and ganglion cells in Rhesus monkey¹⁹.

My results show that rod signals influence colour mechanisms. Rod and cone signals converge onto single ganglion cells in the monkey²⁰, and many ganglion cells have a receptive field that receives an excitatory signal from either red, green or blue cones in the centre and an inhibitory signal from a different cone type in the periphery²¹. Similar mechanisms are found in the lateral geniculate nucleus (LGN), and many of these units undergo a Purkinje shift when dark adapted, thus showing a rod input²². Ganglion and LGN cells have circular receptive fields; however, many units in the striate cortex are sensitive to line orientation and colour²³. The cortical units have receptive fields whose excitatory and inhibitory areas receive inputs from the same cone type²⁴, and thus they are highly sensitive to the spatial properties of a red or green pattern—unlike the precortical cells. Adaptation to a coloured grating might thus depress sensitivity in cortical cells tuned to the adapting colour, orientation and spatial frequency. A test pattern of the same orientation and spatial frequency would then produce less response in these units, and this imbalance may signal the complementary colour. Rod signals may also converge onto these mechanisms, and thus the colour effect may be seen at scotopic levels.

Infantile obesity and later weight control in the baboon

RECENTLY widely quoted studies imply that overfeeding in infancy is associated with increased formation of adipose cells and predisposes to obesity later in life. This has been documented for newborn rats in whom the high adipose cell count persisted after overfeeding was discontinued¹. In rats which had been fed sparsely as newborns for up to 21 d, the fat cell count did not increase when they were fed more generously later. The establishment of regulatory controls over food intake has also been related to early experiences.

Rhesus monkeys raised in isolation and then given access to unlimited food were found to overeat to the same degree as monkeys with hypothalamic lesions². Clinical observations suggest that the inability of some obese people to control their food intake is related to deficits in early learning experiences, with inability to differentiate between nutritional need and other signs of discomfort³. Experimental observations have confirmed that obese and normal subjects differ in their eating responses to internal and external cues⁴.

We report here evidence which casts doubt on the prevailing opinion. Using a group of baboons (*Papio* sp.) raised in the laboratory, some of whom had been fat as infants, we have been able to evaluate the relative importance for later weight regulation of excessive fat formation in infancy and of defects in the regulatory mechanisms. No adipose cell count was done during the period of infantile obesity.

The baboons were delivered by Caesarean section within a 6-week period, with birth weights ranging from 0.65 to 1.1 kg. They were fed a mixture simulating the composition of natural baboon milk, which was given by bottle at scheduled intervals in measured amounts to insure normal growth and weights⁵. This liquid diet was composed of a commercial human infant formula, SMA/S-26 (Wyeth), water and corn oil in the ratio of 90:80:1. At the end of the first month some infants were put on a self-feeding device, permitting *ad libitum* feeding; these animals gained excessive weight and became visibly fat⁶. After 7 to 8 months all animals were weaned gradually on to solid food, a commercial monkey biscuit which was approximately

Fig. 1 Weight of baboons during infancy. The heavy lines represent three animals on a self-feeding device; the onset is indicated by the first arrow (↓). The dotted lines show the weights of three animals on measured feeding. The second arrow (↑) indicates onset of gradual weaning of all animals to solid food.

25% protein, 5% fat, 4.5% fibre and 3% mineral. The weight gain of the fat infant baboons slowed down. All animals were weighed regularly every month.

From birth until 1 month of age these animals were housed in stainless steel boxes and were then transferred to conventional stainless steel primate cages. They were kept singly but could hear and see each other in rooms which housed several baboons. They were cared for by a minimum number (two or three) of animal care personnel which remained the same during the whole period.

For our experiment we used approximately 2.5-yr-old animals (pre-puberty): three had formerly been obese, and three, which were of equal age and had not been fat as infants, served as controls. Figure 1 shows the patterns of weight gain in these

Table 1 Weekly changes in weight on *ad libitum* feeding

Figures are kg. *Ad libitum* feeding began on July 6 and measured feeding recommenced on October 5.

six animals during infancy. Animals on the self-feeding device had a slightly higher birth weight, 0.9 kg as average, compared with an average of 0.73 kg for the others. On the self-feeding device weight increased at an excessive rate, and reached 110% of birth weight at the end of the fourth month and 190% at the end of 6 months. The corresponding increases for the animals on measured feeding were 75% and 130% respectively. At 12 months, the weights of all animals were in the same range.

Our experiment consisted of offering an inexhaustable food supply by keeping the food containers filled with monkey biscuits at all times. Two to three times as much food was consumed by the experimental animals than by those on measured laboratory feeding. Because of the wasteful feeding habits of baboons, it was not possible to measure the exact amounts eaten. The rapid gain in weight reflects the greatly increased food intake. Animals were weighed weekly (Table 1). Total body weights during and following the experimental period are shown in Fig. 2. The overall weight gains during the 3 months of the experiment were very similar for five animals—20 to 23% of the starting weight. One animal (No. 6) who had gained weight rapidly during the preceding month,

gained only 12%. Three other baboons of similar ages who continued on the measured laboratory feeding, showed only 4% weight gain during this period.

When excess feeding was discontinued and the animals were again given measured amounts, there was rapid loss of weight during the first week and gradual loss of weight and then stabilisation during the next few months; patterns were similar for all animals.

We found that with access to an unlimited food supply, the formerly fat and nonfat animals reacted in the same way. They all ate excessively and gained weight at a similar rate. Although the immediate control over food intake seemed deficient, as had been described for monkeys raised in isolation², there seem to be limiting regulatory mechanisms for what can be assimilated, without recognisable difference in the formerly fat and nonfat animals.

The lack of difference in the rates of gain and loss between the formerly fat and nonfat animals contrasts with expectation according to reports for experimental rats on excess feeding during infancy. In baboons the later rate of weight gain, and partial retention of the excess weight, is for all practical purposes identical in formerly fat and nonfat animals. Perhaps over-feeding was not continued long enough to cause changes that would influence eating patterns and facilitate fat storage later on. This is in agreement with clinical observations. Though it is true that infantile obesity is frequently followed by life-long obesity, this occurs only when the conditions that make for over eating and obesity persist⁷.

This research was supported in part by a grant from the US Public Health Service.

Evidence from Lincolnshire of the age and intensity of the mid-Devensian temperate episode

THE study of fossil beetles from several sites has indicated a period of temperate climate in the middle of the Devensian (Weichselian)¹. Upton Warren (Worcestershire), dated at about 42,000 yr BP, yielded an assemblage composed, in part, of thermophilous beetles². At Four Ashes (Staffordshire) deposits of the same age which contain warm species overlie Devensian silts of arctic aspect³. A further warm fauna of this age has been investigated from Isleworth, Middlesex (personal communication from G. R. Coope). New faunal and ¹⁴C evidence from this critical period of mid-glacial climatic change is currently being investigated from Tattershall Castle Pit, Lincolnshire (map ref. TF570210).

At this pit organic horizons of several ages lie in sands and gravels above a till rich in Jurassic and Cretaceous erratics. The lowest organic deposit, a shell marl containing a terrestrial snail fauna characteristic of open conditions, may be of Upper Wolstonian age (personal communication from J. G. Evans). This is overlain by compact woody peat assigned on pollen evidence to subzone Ip IIb of the Ipswichian interglacial (personal communication from L. Phillips). An extensive beetle fauna extracted from this peat includes non-British beetles such as *Brachytemnus submuricatus* Schön. and *Valgus hemipterus* L. previously recorded from interglacial deposits^{4,5} and *Isorhipis melasoides* Lap. and *Pycnomerus terebrans* Ol., species noted in Postglacial deposits^{6,7} but now extinct in Britain⁸. Wood-boring genera such as Cerambycidae and Scolytidae are well represented and species of Anobiidae include *Xestobium rufovillosum* (Deg.), *Anobium fulvicorne* Sturm and *A. punctatum* (Deg.). Examples of other tree-dependent species, *Melasis buprestoides* (L.), *Dryophthorus corticalis* Pk., the oak leaf-miner *Rhynchaenus quercus* (L.) and the predators *Colydium elongatum* (F.) and *Dasytes plumbeus* (Müll.), demonstrate the presence of mature, mainly deciduous forest. Other environmental factors—rich humic soils, areas of marshy vegetation, influent streams and in particular, warmer summer temperatures than in South England today—are indicated by this interglacial fauna.

Above this peat are two mid-Devensian organic silt horizons. The lower of these, which occurs within frost-disturbed gravels or directly on the peat, has ¹⁴C ages of 42,100 ⁺¹⁴⁰⁰/₋₁₁₀₀ yr B.P. (Birm 309) and 44,300 ⁺¹⁶⁰⁰/₋₁₃₀₀ yr BP (Birm 408), and it has yielded a cold, impoverished fauna. Characteristic foreign species include *Diachila arctica* Gyll., *D. polita* Fald. and *Dyschirius septentrionum* Munst. (Carabidae), *Helophorus obscurus* Popp. and *Ochthebius kaninensis* Popp.⁹ (Hydrophilidae), *Olophrum boreale* Pk., *Boreaphilus henningianus* Sahlb. and *B. nordenskiöldi* Pk. (Staphylinidae). These are now largely confined to areas of high latitude or extreme continentality. Several other species are now restricted to Northern Britain. This fauna indicates tundra conditions, with tracts of sterile soil between low plants and ephemeral ponds.

Stratigraphically above and thus demonstrably younger than this 'arctic' silt is a more continuous horizon which has yielded a remarkably thermophilous fauna. Its ¹⁴C ages of 43,000 ⁺¹⁴⁰⁰/₋₁₁₀₀ yr B.P. (Birm 341) and 42,000 ± 1,000 yr BP (Birm 409), apparently overlapping those of the 'arctic' silt, underline the closeness in age of the two horizons, despite their marked faunal contrast. Noticeable among the several hundred species which make up the warm assemblage are certain non-British beetles such as *Hydrochus flavipennis* Kust. (R. B. Angus, unpublished work) which is today found in Southern Europe and *Aphodius bonvouloiri* Har., now found only in Spain. *Pseudocleonus cinnereus* Schrank and *Chrysolina limbata*

L. are Central and Southern European species, and *Helophorus discrepans* Rey lives in East Europe and at high altitudes in Spain. A high proportion of the species today found in Britain, including *Nebria livida* (L.), *Porcinolus murinus* (F.), *Crypticus quisquilius* (L.) and *Otiorrhynchus ligustici* (L.) occur only in the southern half of the country. Clearly this assemblage requires average July temperatures at least as high as those of South England. Despite the occurrence of certain East European species, there is no evidence for marked continentality and it is unlikely that the total fauna would survive particularly low winter temperatures.

The duration of this warm, mid-glacial episode was short. A cold, continental fauna from deposits of 39,300 ⁺¹³⁵⁰/₋₁₁₆₀ BP (Birm 333) at Queensford, Oxfordshire (G. R. Coope personal communication) indicates that a considerable degree of cooling had occurred by this time. At Tattershall the reduction in the numbers of thermophiles in successively younger samples from this horizon may be the result of falling temperatures. The structure and ecological requirements of this interstadial fauna provides further evidence of the shortness of this climatic oscillation; this may be illustrated by comparison with the earlier interglacial fauna. Both assemblages indicate warm conditions at the time they were deposited, but the mature, deciduous forest habitat of many of the interglacial beetles obviously developed during a long period of climatic stability. Such vegetation maturity is not demanded by the interstadial fauna which is largely composed of species that feed on low plants and grasses, as well as abundant Scarabaeidae associated with the large mammal population which grazed the area. This insect fauna, able to respond rapidly to climatic change by colonising a newly favourable area⁴, lacks any species whose habitats require a long period of development. In particular, tree-dependent species are absent although temperatures were high enough to permit forest growth. This fact, while dispelling any idea that this fauna is interglacial, supports the stratigraphical and radiocarbon evidence of its mid-glacial age.

I thank Dr R. B. Angus, Dr G. R. Coope and Mr P. J. Osborne for help with this project, and Professor F. W. Shotton for reading this manuscript. This research is being undertaken during the tenure of a Natural Environment Research Council grant.

book reviews

Second generation environmentalists

Environmental Issues: Population, Pollution and Economics. By Lawrence G. Hines. Pp. ix+339. (Norton: New York, December 1973.) \$9.75 cloth; \$3.25 paper.

Society and the Assessment of Technology: Premises, Concepts, Methodology, Experiments, Areas of Application. By F. Hetman. Pp. 420 (OECD: Paris; HMSO: London, 1973.) 38 francs; £3.36; \$9.50.

NEITHER of these books is an original contribution to knowledge, but they are nevertheless both very useful. They reflect the extent to which environmental concerns and technology assessment have become part of normal policy making and analysis. The typical early literature of this genre had an evangelistic and strong emotional tone, which was often conveyed in the title as well as the text. One thinks, for example, of *Our Plundered Planet*, *Silent Spring* and the *Population Bomb*.

Both of these books belong emphatically to the second generation. Not that they are lacking in concern; Hines in particular makes quite explicit the strength of his attachment to the preservation of natural amenity and wilderness. But both are very much alive to the complexity of the issues and the trade-offs which are inevitably involved. This means that they are rather duller books than the best of the pioneering single-minded first generation advocacy; but as against this they are much more realistic and much more acceptable to administrators.

The scope of Hines's book is wider than that of Hetman's in one sense: its first section is devoted to the world population and resource problem brought into the limelight by the MIT "World Models". His sceptical critique of the MIT work, although much less thorough than that of the Sussex Science Policy Research Unit, comes to similar conclusions. The second part deals with problems of cost/benefit analysis and the third part with policies to combat pollution. Hetman's book does not discuss the "Limits to Growth" problem at all, nor does it discuss specific policies in relation to pollution. It is devoted entirely to a critical review of the various techniques of 'technology assessment' of which 'cost-benefit' is treated as one example.

Although there are important similarities,

the books differ greatly in style and presentation. Hines's book is far better written, and does not suffer from poor translation into the curiously effete and de-humanised English jargon of the international bureaucracies. The Hines book is far better produced and edited, and the diagrams, tables and references are of a standard to which we have become accustomed in the best American college textbooks. The OECD publication by contrast is rather poorly produced and many of the tables are clumsy. Some of them (for example, Tables 15 and 16) are simply long quotations from other sources.

This is a misfortune as Hetman's book has some outstanding merits. It manages to synthesise a great deal of information about the burgeoning technology assessment movement. It is very balanced in its own assessment of the various techniques and sensible in its awareness of their strengths and limitations. It avoids the temptation of staking everything on one particular technique—a fault which bedevils so much of this literature. Finally it recognises the importance of the political process in relation to any technique or combination of them. In its all-round grasp of a very complex problem the book compares very favourably with much of the American technology assessment literature. It is therefore a thousand pities that the book is so badly edited and produced. It is too long, often repetitive and sometimes unreadable. The two greatest faults are first: the inclusion of large chunks of material (especially in chapter 3) which should have been relegated to an appendix or the (otherwise excellent) reference list. Second, the failure to bring the book to life by thorough discussion of some real-life cases such as the third London airport or supersonic transport. Many examples are cited, but the form of citation is long enough to be boring but not thorough enough to give the full flavour and excitement of a real political problem. Perhaps these faults may be partly attributed to the inevitable limitations of publication through an international organisation, but the OECD has sometimes been outstanding in its toleration of lively and critical material (even when it was embarrassing to member governments) and in the quality of its publications.

By contrast, one of the best chapters in the Hines book is on the "Middle Snake River Hydro-electric Project". This makes the essential points far better than any theoretical analysis, since it shows so clearly just how cost-benefit analysis was manipulated in practice to serve particular interest groups, and the real practical difficulties involved in the attempt to put a market valuation on some of the intangibles. Hines is a competent professional economist but he has taken the trouble to learn a good deal about water and air pollution, and he therefore makes a modest success of his ambitious goal to transcend the normal disciplinary boundaries of economics. One must hope that this approach will become a new fashion in economics, either through interdisciplinary teams or by the individual efforts of men like Hines. He explains in a lucid, albeit very elementary manner, the failure of the market mechanism in decisions about the environment, and the inevitability of public responsibility and policy. In this respect, of course, his book is a welcome return to an old fashion: the original classical discipline was political economy.

C. FREEMAN

Tetrahymena

Biology of Tetrahymena. Edited by Alfred M. Elliott. Pp. x+508 (Dowden, Hutchinson and Ross: Stroudsburg, Pennsylvania; Wiley: Chichester, December 1973.) £19.25.

OF all the protozoa *Tetrahymena* is probably the most studied genus. *T. pyriformis* (formerly called *Glaucoma pyriformis*), which occurs in ponds and streams the world over, was first successfully cultivated axenically, that is, in the absence of the other organisms which comprise its normal diet, in 1923 by André Lwoff. By 1951 Kidder and Dewey had succeeded in growing it in a chemically defined, though very complex, medium. Later developments have been the discovery by Elliott and his colleagues of mating types of *Tetrahymena*, following similar work in *Paramecium*, thus opening up the possibilities of doing genetic work, and these have been exploited by Nanney, Allen and others. On technical grounds, however, *Tetrahymena* has turned out to be rather less suited to

genetic experiments than *Paramecium*, though for biochemical work *Tetrahymena* is far superior. Finally *Tetrahymena* has recently been used for developmental studies, especially of the elaborate surface patterns of basal bodies, cilia, oral apparatus and so on. Thus the organism is now available for many different kinds of work, and a general review of the current state of knowledge about it would be very valuable.

This volume consists of some thirteen chapters written by about as many specialists and ranges over the taxonomy, cytology, life cycle, biochemistry, genetics and cortical development of the organism, with a final chapter on *Tetrahymena* as a nutritional and pharmacological tool. The styles of the different chapters are very diverse, from the relatively prosaic descriptive accounts of the taxonomy, life cycle, and some of the biochemistry, to far flung speculations in the genetics chapter of Allen and Gibson. Little attempt seems to have been made to interrelate the material in different chapters, and there is a certain amount of overlapping. The book is really a series of separate articles, tied together only by the fact that the same organism is mentioned in all of them. Viewed in this way, it is a useful source of information about the state of knowledge of various special topics in 1972

or slightly earlier, and for anyone planning to use the organism experimentally, it is essential reading.

The chapter by Frankel and Williams on "Cortical Development" is very comprehensive and clear, and the book ends with a bibliography prepared by Dr Elliott, after consultation with John Corliss, of no fewer than 1,700 citations stated to comprise all major and most minor publications on *Tetrahymena* up till 1972. This is one of the most valuable features of the book.

It seems to me that research on *Tetrahymena* may be approached from two opposing viewpoints. The first involves using the organism as a model cell whose behaviour resembles closely enough that of higher animals to enable it to be used for trials of pharmacological and dietary substances intended for use on higher animals or man. This is discussed in the final chapter by Hutner and others. It seems that one should be cautious in accepting the results of such trials, especially of drugs suspected of having carcinogenic, toxic, or other harmful effects on human cells, though the use of *Tetrahymena* as an agent for assaying preparations of particular amino acids or vitamins which are an essential requirement in its diet is more reliable.

The second approach to research on *Tetrahymena* is to study it for itself, as a remarkably interesting biological system, with many technical advantages for experimental work, helping us to understand all sorts of biological processes, whether biochemical, genetic or developmental. Here it does not matter so much that *Tetrahymena* differs markedly from cells of higher animals, for example in its presence of two kinds of nuclei, its extraordinarily elaborate surface structures, and finally its 'protozoan' nature—compressing all life processes into one and the same compartment.

Biologists expert in other matters, or those with more general interests, would be disappointed to find in this volume so little effort at assessing the overall importance of the work, and no attempt at all to write a single coherent account.

G. H. BEALE

Resistant plants

Breeding Plants for Disease Resistance: Concepts and Applications. Edited by R. R. Nelson. Pp. xii+401. (Pennsylvania State University: University Park and London, November 1973.) £6.85.

PLANT diseases are major factors limiting agricultural production throughout the world. Resistant varieties, which are less damaged by disease than others, are widely used to control diseases. This book attempts to summarise the

present state of our knowledge concerning the production of resistant varieties, with particular reference to some of the most economically important crop species.

The book is divided into two main parts. In part 1 the editor gives his views (many of which he admits are controversial) on the concepts, principles and terminology of breeding for disease resistance. Part 2 consists of sixteen chapters in each of which work on breeding for resistance in a particular crop species is summarised. Each chapter has been written by specialist pathologists, geneticists and plant breeders, mainly from the United States, with research experience in that crop. The format of these chapters varies from crop to crop but generally involves a short introductory section on the origin, economic importance and breeding system of the crop concerned and a description of the main sources of disease resistance. This is followed by accounts, which are often extremely brief, of breeding for resistance to some of the main virus and fungus diseases of the crop. An example of this brevity is afforded by the chapter on disease resistance in peas in which there are subsections on eighteen diseases in less than seventeen pages. Conversely, the chapter on soybeans deals in much greater detail with only four diseases in fourteen pages.

This lack of uniformity of treatment in different chapters can be disconcerting but is perhaps to be expected in such a compilation by so many authors, each with a different style and approach. It would have been useful if the editor had written a third part in which he attempted to draw general conclusions from the experiences described in the crop chapters, particularly in relation to the theoretical considerations outlined in part 1. As it is, the reader is left to draw his own conclusions from work on sixteen different crop species.

I find it surprising that a book of this nature includes no line drawings or photographs. Illustrations of disease symptoms and of examples of differences between resistant and susceptible varieties after exposure to infection would have been particularly interesting and useful. As a result of editorial policy, the book contains remarkably few references to original published work on disease resistance. A less restricted bibliography would have made this a much more useful reference book.

In spite of its limitations and shortcomings, this book is an up-to-date, authoritative account of breeding for resistance to diseases. As such it deserves to be read by all those concerned with plant pathology and plant breeding.

G. E. RUSSELL

Ions into solids

Ion Implantation. By G. Dearnley, J. H. Freeman, R. S. Nelson, and J. Stephen. P. xv+802. (Defects in Crystalline Solids, vol. 8.) (North-Holland: Amsterdam and London; Elsevier: New York, 1973.) Dfl. 225; \$79.

EVER since it was found possible to generate beams of energetic ions, investigators have been directing them into solids, and noting the effects. As expected, a set of complex but interesting phenomena was to be found in the interaction of the beam with the solid; moreover, it was soon realised that implantation was a useful method of modifying solids, while ion channelling was a unique diagnostic tool. A mushroom of literature on the subject developed in the late 1960s.

An anticipatory thrill is thus in order when one opens a book in which four authorities at a centre like AERE, Harwell, have combined to try and review the field, especially when the weight and thickness of the book indicate that the coverage is likely to be broad and the treatment detailed. The main question then is not of accuracy or authority—these are taken for granted—but whether the authors have done their reading public the maximum service in digesting and explaining this great expanse of literature as well as bringing out salient points of their own research. My impression as a user of ion-implanted specimens is that they have certainly made a very good attempt at dealing at some depth with the physics and engineering aspects which relate to the uses of implantation. What failures there are will be felt more by those looking for insight and some are discussed later.

The book consists of four main sections, each attributed to one of the authors, followed by a shorter chapter on the less usual applications. Apart from the unavoidable lack of unity which this method gives, the sections have been well coordinated as to subject matter, level of discussion, graphics and so on, although there is little cross referencing. Only a few things fall between the cracks; for example all of the authors are mainly interested in ion implantation into metals or semiconductors, so that insulators are given very little space. The fact that each author is treating his special field also means that he writes at a rather high intellectual level and pace and (with the exceptions described below) rarely catches his breath to explain to lesser mortals what the inwardness of some statement may be. For example, one author remarks that metals, unlike semiconductors, remain crystalline under bombardment even up to several hundred

displacements per atom, and that the reason for this fundamental division in ion-bombardment effects is not known. Surely, between the four authors, is not some little speculation on the reasons desirable? One can certainly form some hypothesis on the question in terms of the kinetics and type of vacancy/interstitial recombination available in the two forms of solids. Indeed, throughout, few panoramic views of the subject are essayed.

The author of the first main section, on ion penetration and channelling, is both the most concise and the most willing to comment intelligently on the meaning and prospects of the research work discussed. For example, the very useful phenomenon of radiation-enhanced impurity diffusion is made more than usually fascinating by useful asides. The discussion of channelling is, as expected, masterly. The next section, on the physical state of ion-implanted solids, is also a good exercise in compression; perhaps too compressed, since some omissions can be felt. Here was the place for a discussion of the annealing of clustered defects, with all the physical insight which this technique gives. The annealing of metals, bombarded, say, with deuterons at low temperature, yields an important insight into ion damage. Yet the whole topic of annealing of metals is dismissed in one page. This author indeed explicitly limited his writing to the effects observed from irradiation at or above room temperature, and this artificial barrier itself depreciates the value of the section in giving physical insight into the structure of implanted solids.

The third section is a detailed description of the art of implanting. Ion sources, analysers, accelerators and targets are described by a past master of the art and a tabular appendix lists the practical needs of each element in the periodic table. This section is a handbook in itself, unique in that many engineering aspects of ion beam production are only to be found in theses or specialist reports. With its high content of unpublished Harwell data, it probably merits its 200 pages but its length, of course, contributes to the horrendous price of the book.

The fourth part is of similar length, and is on the use of implantation in semiconductor device fabrication. This application has dominated all others to date and it can be claimed that a comprehensive review here is justified on those grounds. But the argument of rarity, used above, does not apply in this case. Should this section perhaps have been clipped to 120 pages? Coming after many published research reviews, it probably should have; however, in itself, this section is still a very well informed and complete ac-

count and can be thought of as the United Kingdom's brief on the subject of implantation in silicon. The final chapter, on other applications of implantation, is a useful compilation.

When a work so significant appears at such a price the reviewer must also try to advise librarians as to whether it is a good buy. I have already told my librarian that it is, and to others would say that, like Harris tweed, the price may hurt but the goods will give long and unwilting service.

A. G. HOLMES-SIEDLE

Nature and nurture

Introduction to Behavioral Genetics. By G. E. McClearn and J. C. Defries. Pp. 349. (Freeman: San Francisco, 1973.) \$10.

SOME of the most important developments in the interdisciplinary field of behaviour genetics have occurred in the thirteen years since Fuller and Thompson's *Behavior Genetics* provided the first and, until now, the only comprehensive coverage of the subject. The publication of *Introduction to Behavioral Genetics* under the joint authorship of a geneticist and a psychologist is, therefore, particularly welcome.

The introduction puts the emergence of the central problem of behaviour genetics, the nature-nurture controversy into historical perspective and the final chapter reviews the current status of this controversy as it relates to human behavioural differences that contribute to social problems. In the intervening pages the basic principles of genetics are introduced and these are elaborated as necessary throughout the rest of the book. A brief account of basic statistical principles that stops short of the analysis of variance precedes the presentation of examples from the behavioural genetics literature. These are grouped under a number of headings according to whether one or many genes are involved, whether experimental breeding or cytological observation were the means of investigation, and whether the main interest of the results obtained relates to the biochemistry of gene action, the processes of development or the forces acting on natural populations. A chapter wholly devoted to quantitative genetics, which in content and approach owes much to Falconer's *Introduction to Quantitative Genetics* reflects the present day emphasis on quantitative differences in behaviour.

Though the authors can rightly claim to have produced an introduction to the entire range of behaviour genetics, they have done so, to some extent, by offering *ad hoc* solutions to the immediate issues raised by the

behavioural examples rather than using well-chosen examples to develop and illustrate the experimental methodology and the principles underlying the analytical procedures and interpretations. It is difficult to believe that more appropriate examples could not have been found or that they could not have been used more effectively to illustrate the principles of experimental design, model building, hypothesis testing, interpretation and prediction. These are, however, relatively minor deficiencies compared with the advantages of having a concise, up to date account of the subject.

J. L. JINKS

Deformed embryos

Environment and Birth Defects. By James G. Wilson. Pp. xiv+305. (Environmental Studies: an Interdisciplinary Monograph Series.) (Academic: New York and London, December 1973.) £9.10.

THOUGH mortality at all ages in the period of childhood and adolescence has fallen dramatically during the past few decades mortality from congenital defects has shown little change. The relative importance of congenital defects has increased and continues to increase. This applies both to mortality and morbidity. Knowledge on the aetiology and underlying pathogenesis of congenital defects is very limited and much of the information available is widely dispersed in the literature. A book which brings together and unifies much of the existing information on teratology—defined as the adverse effect of environment on developing systems—is to be welcomed and fills a gap in the medical and biological literature.

The book begins by identifying the broad issues in teratology including the basis on which the conceptus becomes susceptible to adverse effects; the disturbance of cellular tissue and developmental processes which constitute the basic pathology of teratology; the importance of accessibility of an agent to the conceptus in determining possible teratogenic effects; dose effects; and the possible range of manifestations of deviant development. The causes of developmental anomalies are discussed in terms of genetic influences, chromosomal aberrations, radiation, chemicals and drugs, dietary imbalance, infections, respiratory gas levels, extremes of temperature, metabolic or endocrine imbalance, physical trauma, mechanical factors, placental factors, antibodies and combined effects. A review of the various drugs known or suspected to cause congenital malformations (not entirely complete) is relevant to clinical pharmacology and it touches on the

possible teratogenic effects of environmental chemicals used in industry and in agriculture.

The book then goes on to discuss the means by which developmental defects occur—the mechanisms of teratogenesis—under the headings of mutation; chromosomal non-disjunction and breaks; mitotic interference; altered nucleic acid integrity or function; deficiency of precursors, substrate and enzymes; altered energy sources; enzyme inhibition; osmolar imbalance; changed membrane characteristics; excessive cell death; reduced cell proliferation; disturbed interaction between cells; and reduced migratory movement of cells. Figures are given for the general incidence of developmental defects in man based on differing assessments made on embryos, stillbirths, neonatal deaths and later deaths. The effect of teratogenic processes is classified into four categories, namely, intra-uterine death, malformation, growth retardation or functional defect.

There is a useful account of the early developmental stages of the human ovary and foetus with pictorial representation of 23 different stages from fertilisation to the 53rd day of gestation, and a discussion on the concept of critical periods of susceptibility.

Further chapters deal more specifically with the access of teratogenic agents to the foetus and the foetal defence mechanism against them, and with the means of detection of teratogenic effects in man including recognition based on observation of clusters of cases, epidemiological surveys and surveys of high risk populations.

The last quarter of the book deals largely with the contribution of animal experiments to the assessment of human teratogenic risk and to the problems which arise from such experiments. The latter include the differing effect caused by the timing of any insult, dose effect in respect of quantity of teratogen and duration of administration, the masking of teratogenesis by embryolethal effect and standards of recognition of defects. There is a section on the various animals which can be used in teratology testing. The author puts forward a suggested scheme of teratogenic testing based on the graded use of animals of different availability and cost. Lastly there are special sections on appropriate literature relative to a number of individual animals and there is a valuable general bibliography.

This book ranges over the field of teratogenic response to the environment as revealed by animals and human studies. It concentrates primarily on the broader biological issues of teratogenesis approaching the subject from a morphological rather than a biochemical standpoint. The principles of

teratological testing are discussed and the author's own recommendations regarding his scheme for animal testing of suspect drugs provides a special component to the discourse. The book is clearly and concisely written and will prove a very valuable source of information to a wide range of those who are concerned with the environment and its possible effect on human development. These would include environmental scientists, hygienists, developmental biologists, obstetricians and paediatricians, toxicologists and pharmacologists. JOHN O. FORFAR

Mathematical brainwaves

Automation of Clinical Electroencephalography. Edited by Peter Kellaway and Ingemar Petersén. Pp. viii+318. (Raven: New York; North-Holland: Amsterdam, 1973.) \$22.70; Dfl.59.

THIS book provides an excellent guide to the quantitative methods of analysis currently being employed in EEG research. In the opening chapters, the editors draw attention to the major problem involved, namely that of defining the standard method of visual analysis in mathematical terms. For the non-clinician, a comprehensive description of standard EEG analysis is included, together with examples of typical wave forms and commoner abnormalities.

The case is presented for regional centres for automatic EEG analysis, so that research methods described can be widely applied to clinical practice. To implement this programme, a telemetry system capable of carrying at least eight channels of information would be required, a suitable system operating by public telephone being described later in the book. Continuing this theme, methods are described enabling multichannel EEG data to be presented in a simplified form on a single page, either by bar graphs for the principal frequency bands (delta, theta, alpha, beta), or by compressed spectral array, neither technique requiring as experienced an interpreter as conventional paper records. Extensive data reduction is involved, and although the two methods are complementary, they are suitable only as screening tests, and not as replacements for conventional EEG techniques. The method and application of Fast Fourier Transform are considered, and among many other topics included are pattern recognition techniques and EEG analysis in sleep.

The book is well presented and clearly illustrated throughout, and should prove a valuable reference work for those with interests in this expanding field. L. M. BRANCH

APPOINTMENTS VACANT

DIRECTOR

The Jackson Laboratory invites applications for the position of Director of the Laboratory, which will become open on October 1, 1975. Qualified applicants are invited to submit a curriculum vitae and summary of experience to one of the following:

Dr James D. Ebert, Chairman, Search Committee, Marine Biological Laboratory, Woods Hole, Massachusetts 02543;

Dr James F. Crow, Member, Search Committee, Department of Medical Genetics, University of Wisconsin, Madison, Wisconsin 53706;

Dr Douglas L. Coleman, Secretary, Search Committee, The Jackson Laboratory, Bar Harbor, Maine 04609.

AN EQUAL OPPORTUNITY EMPLOYER. (3)

INFORMATION SCIENTIST

required to prepare input and abstracts for the monthly abstracting journal "Aquatic Sciences and Fisheries Abstracts", and to assist in the general running and development of the Marine Pollution Information Centre. Applicants should be science graduates with relevant qualifications or experience in information work. Salary on the Civil Service scale for Scientific Officers, £1,435 to £2,329 (max) (under review). Applications, giving full relevant details and naming two referees, or requests for further information, should be sent to: The Librarian, Marine Biological Association of the United Kingdom, Citadel Hill, Plymouth PL1 2PB, Devon. (294)

STAFF VACANCY OXFORD ENGLISH DICTIONARY

Applications are invited for a new full-time appointment as:

RESEARCH ASSISTANT (Science)

for A SUPPLEMENT TO THE OXFORD ENGLISH DICTIONARY, now in preparation at Oxford (Volume 1, A-G, published in 1972). The successful applicant will be required to investigate the history and usage of terms from all branches of science, using the resources of the Oxford University libraries. A degree in science is essential. Salary in accordance with experience and qualifications, but not normally less than £1,667 per annum, with participation in Clarendon Press superannuation scheme.

Further particulars from:

The Personnel Department (KB),
The Clarendon Press,
Walton Street,
Oxford OX2 6DP

to whom applications should be made in writing, with curriculum vitae and the names and addresses of two referees, by August 5. (293)

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF ZOOLOGY

Applications are invited for the post of EXPERIMENTAL OFFICER IN ZOOLOGY tenable from September 1, 1974, to assist in research (directed by Dr K. C. Highnam) into the endocrine control of development and reproduction in insects. Salary Range: £1,596 to £2,340 (£1,707 to £2,505 from October 1, 1974). Further particulars from the Registrar and Secretary, The University, Sheffield S10 2TN to whom applications (3 copies) should be sent by July 31, 1974. Please quote reference R110/G. (269)

E.E.C. RESEARCH CENTRE ITALY

The E.E.C. Research Centre at Ispra (near Lake Maggiore in Italy) is seeking to fill the following posts:

Head of Engineering Service

This service, totalling about 20 persons, is comprised of university graduates and design draughtsmen divided into groups dealing with reactor physics, instrumentation, mechanical design and project engineering.

Candidates must have a good university degree, preferably in engineering, but a physicist or chemist with suitable experience would also be considered.

At least 10 years' experience in nuclear engineering is required, preferably with water reactors and, if possible, with in-pile loops. Approximately half of this time should have been spent in a position of responsibility with resultant capability to lead a group of qualified engineering personnel.

Good knowledge of French, Italian or English is required with a fair knowledge of at least one of the other two languages.

Radiochemist

for work involving research in the field of transuranium and transplutonium elements separation by solvent extraction or other methods.

Candidates should be under 35 years old and university graduates or postgraduates with at least two years' radiochemistry experience.

Senior Technical Assistant (Engineering Technical Assistant)

for the Fracture Mechanics Group (Reactor Safety Programme) of the Technology Division, to be responsible for the standard destructive mechanical tests that are carried out on specimens (tensile strength, hardness, impact strength, Pellini, etc.); to devise and carry out fracture-mechanics tests (COD, K_{IC}, I, etc.) and to devise non-destructive methods of stress-strain measurement (Moiré, photo-elasticity, etc.).

Candidates should have a Higher National Diploma, Higher National Certificate or equivalent, in mechanical engineering and at least five years' experience of destructive mechanical testing and/or stress-strain measurement. Additional experience of data processing would be an asset.

Radiochemical Technician

for radiochemical work in glove-boxes on transuranium and transplutonium elements.

Candidates should be HND graduates in applied chemistry with radiochemistry elements and have achieved practical experience preferably in a radiochemical laboratory.

In all cases, contract will be initially for two years, probably renewable for a further year.

Application forms and further details of the terms and conditions of employment, which compare well with national scientific institutions, may be obtained from: Mr. P. Blaes, Personnel and Administration Division, Commission of the European Communities (Euratom), Ispra (Varese), Italy.

Completed application forms, indicating the post for which you wish to be considered, should be received at the above address by 19th August, 1974.

(267)

KINGSTON POLYTECHNIC SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES RESEARCH ASSISTANT

required to study ultrasonically-induced damage in biological material and the mechanisms by which this occurs. You will be encouraged to register for a higher degree. Applicants should be honours graduates in a physical science or biology. Salary £1,427 to £1,537 (under review). Further details and application forms from Appointments Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. (287)

UNIVERSITY OF LEICESTER DEPARTMENT OF CHEMISTRY

Applications are invited for the post of RESEARCH TECHNICIAN (Grade 3) to carry out manipulation on a high vacuum line and to operate an Electron Spin Resonance spectrometer. H.N.C. or a degree would be an advantage but other applicants with appropriate experience will be considered. Apply to Dr J. B. Raynor, Chemistry Department, The University, Leicester LE1 7RH, naming two referees. Salary in range £1,650 to £1,920 with threshold agreement. (275)

NEW ZEALAND
Ministry of Agriculture & Fisheries

Applications are invited for the undermentioned vacancy:

SCIENTIST

(BEEF PRODUCTION)

**RUAKURA ANIMAL RESEARCH STATION
 HAMILTON, NEW ZEALAND**

SALARY:

Payable up to NZ\$12,653 depending on qualifications and experience.

DUTIES:

To carry out feeding and management studies with grazed and stall fed cattle. Comparisons are required between the performance of grass fattened and feed-lot finished stock, both relative to physical rates of live weight and carcass gain, and to eating quality of the meat. The influence of rearing systems and the contributions of compensatory growth of beef cattle performance require examination under a wide range of circumstances.

QUALIFICATIONS DESIRED:

Masters degree or higher in agricultural science.

PASSAGES:

Fares for appointee and his wife and family, if married, will be paid.

INCIDENTAL EXPENSES:

Up to NZ\$120 for a single man and NZ\$800 for a married man can be claimed to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London SW1Y 4TQ, with whom applications will close on 22 August 1974.

Please quote reference P/T 104 when enquiring.

(274)

**UNIVERSITY COLLEGE CARDIFF
 TEMPORARY RESEARCH
 TECHNICIAN**

IN THE DEPARTMENT OF ZOOLOGY

Applications are invited for the above position concerned with work on the distribution of animals on the Severn Estuary. Candidates must possess some zoological training, and familiarity with two stroke motors would be an advantage. Duties to commence August 1, 1974. Closing date is one week from the appearance of this advertisement. Salary range £1,524 to £1,794.

Applications, together with the names and addresses of two referees, should be forwarded to The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Please quote ref. 0605. (290)

**UNIVERSITY OF GLASGOW
 RESEARCH ASSISTANT**

Applications are invited from medical graduates, honours or postdoctoral graduates in physiology, pharmacology or biology to undertake an M.R.C. grant-aided project on Neurotransmitter Metabolism in the Cerebral Cortex in the Institute of Physiology. The post is tenable for 3 years from October 1, 1974 and salary range will be £2,118 to £2,412 per annum.

Applications should be lodged with Professor I. A. Boyd, Institute of Physiology, University of Glasgow by August 16, 1974. Further information can be obtained from Dr J. A. G. Watt, Gartnavel Royal Hospital, 1055 Great Western Road, Glasgow G12 0XH.

In reply please quote Ref. No. 3511M. (281)

UNIVERSITY OF EAST ANGLIA

Applications are invited from suitably qualified persons for a SENIOR RESEARCH ASSOCIATE-SHIP in the Climatic Research Unit (associated with the School of Environmental Sciences). A good degree in physics, meteorology or geophysics and previous experience of research and practical work in climatology and/or the global circulation of the atmosphere or oceans is desirable. The work of the Unit is concerned with improving knowledge of the long record of climate, and of global relationships, with a view to establishing predictive techniques and statistical rules based on understanding of the physical processes of climatic variation. Salary on the scale £2,118 to £4,896 according to age and experience. The appointment will be for 3 years in the first instance.

Applications (one copy only), with a curriculum vitae and list of publications, together with the names and addresses of two persons to whom reference may be made, should be sent to the Establishment Officer, University of East Anglia, Norwich NOR 88C, England, and must be received before August 31, 1974. (276)

**UNIVERSITY OF LONDON
 GOLDSMITHS' COLLEGE
 NEW CROSS, LONDON SE14 6NW**

Applications are invited for the post of Technician (Grade 3) in the Geology Department to start as soon as possible.

The person appointed should have a keen interest in geology and preferably be studying for an academic qualification in geology, if not already qualified.

Duties would include:

1. Curating the Departmental map and specimen collection.
2. Thin section making.
3. Photographic and reprographic work.
4. Display work.
5. Attendance at field-classes.

Salary, according to qualifications and experience, within the following range: £1,740 to £2,010 p.a. including £90 London Weighting Allowance.

For further details write, enclosing a stamped addressed A4 envelope, to the Personnel Officer, to whom applications should be sent by August 16, 1974. (272)

**MEDICAL LABORATORY
 TECHNICIAN**

required for expanding diagnostic radioimmuno-assay/saturation assay department. Experience in radioisotopic methods is desirable though not essential, but attention to detail and a high standard of orderliness in laboratory work are very important requirements. Successful candidates will be expected to display initiative and to contribute to the development of new techniques in this expanding and important field. Salary on Whitley Council scale according to age and experience (maximum £2,577 p.a.). Applications including a curriculum vitae and the names and addresses of two referees should be submitted to: Professor R. P. Ekins, Department of Nuclear Medicine, The Middlesex Hospital School, London. W1N 7RL by July 31, 1974. (266)

Find your place in British Gas

SPECTROSCOPIST

A scientist with post-graduate research experience in spectroscopy is required to join a group engaged on R and D in combustion. Work in the group would include the development of laser diagnostic techniques, including Raman spectroscopy, for the study of high temperature flames.

Candidates should be graduates in one of the physical sciences. Starting salary will depend on qualifications and experience, but will be within a scale rising to £3,192 or £3,510 (currently under review).

For further details and an application form, write to Research Secretary, British Gas Corporation, London Research Station, Michael Road, London SW6 2AD, quoting reference 4010/12/NA. (327)

BRITISH GAS

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of Post-doctoral Research Assistant, financed by the S.R.C., to develop some aspects of Affinity Chromatography. Candidates should have an interest in Enzymology.

Applications, stating age, qualifications and experience, together with the names of two academic referees should be received as soon as possible by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/N/276131. (271)

UNIVERSITY OF ALBERTA
DEPARTMENT OF ENTOMOLOGY

Applications are invited for the position of ASSISTANT PROFESSOR, effective April 1, 1975. Qualifications are Ph.D. with postdoctoral experience in insect physiology and interest in aspects of this field applicable to agricultural or forest entomology. Duties include teaching courses in general or applied entomology and insect physiology, the development and direction of a research program and supervision of graduate students in insect physiology and in application of some aspect of physiology to agricultural or forest entomology. Maximum starting salary \$14,043.

Please send full curriculum vitae and names of 3 referees by October 31, 1974 to: Dr George E. Ball, Chairman, Department of Entomology, 260 Agriculture Building, University of Alberta, Edmonton, Alberta T6G 2E3. (297)

UNIVERSITY COLLEGE GALWAY

JUNIOR LECTURESHIP
IN ZOOLOGY

Applications are invited for the above post. Salary scale £2,478 by 99 (10) to £3,468, plus Family Allowances. The closing date for receipt of applications is **August 8, 1974**. Prior to application, further information should be obtained from the Registrar of the College. (308)

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF BOTANY AND
CHEMISTRY
EXPERIMENTAL OFFICER

Applications are invited for the post of Experimental Officer to assist in a research project concerned with the biosynthesis of secondary metabolites in plant tissue cultures. The project is financed by the S.R.C. for a period of two years. Candidates should be graduates in a biological science or chemistry. Salary on a scale rising to £1,647 pds F.S.S.U. depending on experience and qualifications.

Further particulars and forms of application which should be returned immediately, can be obtained from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham. Ref. No. 385. (301)

UNIVERSITY OF KEELE
DEPARTMENT OF PHYSICS

Applications invited for post of Demonstrator to assist with laboratory and tutorial work. Post on year to year basis renewable up to total of three years. Salary £1,815 per annum. Average 12 hours formal teaching per week. Rest of time available for research. Candidates should have good honours degrees. Application forms and further particulars from the Registrar, The University, Keele, Staffs., ST5 5BG, to whom completed forms should be returned by August 6, 1974. (302)

RESEARCH BIOCHEMIST

A vacancy exists in the Lipid Research Laboratory at St Bartholomew's Hospital, London, studying lipoprotein metabolism in relation to Diabetes and Hyperlipaemia. The post would be suitable for a higher qualification (Ph.D. or M.D.). Previous experience in lipoproteins or lipid metabolism would be an advantage. Salary according to age and experience.

Applications with full curriculum vitae to the Personnel Department, St Bartholomew's Hospital, West Smithfield, LONDON EC1A 7BE quoting ref R/4603/N. Closing date August 8, 1974. (312)

Wellcome

Research Technicians

Pirbright, Surrey

We require Technicians or Senior Technicians for our Laboratory at Pirbright, Surrey, to work mainly on the research aspects of the immune response to foot-and-mouth disease vaccine. Candidates should be between 20-25 with ONC, HNC or equivalent qualification and have a biochemical background. Some experience in chromatography electrophoresis and precipitation techniques is desirable.

These posts are permanent and offer a good salary together with excellent conditions of employment.

Please write quoting ref: U/466 and giving brief details of qualifications and experience to the
Personnel Officer,
The Wellcome Research Laboratories,
Langley Court, Beckenham,
Kent BR3 3BS.

(303)

NEW ZEALAND

Department of Scientific and Industrial Research

Applications are invited for the undermentioned vacancy:

SCIENTIST

The New Zealand Oceanographic Institute, Department of Scientific and Industrial Research, Wellington, has a vacancy for a Marine Zoologist to work on shallow water invertebrates in fluctuating environmental situations.

SALARY:

According to qualifications and experience.

DUTIES:

It is envisaged that following some initial survey work, the appointee could concentrate on ecology and/or physiology of selected species which appear indicators of environmental changes due to human activity.

QUALIFICATIONS DESIRED:

Ph.D with good research background as evidenced by published papers, and preferably some post-graduate experience.

PASSAGES:

Fares for appointee and his wife and family, will be paid.

INCIDENTAL EXPENSES:

Up to NZ\$120 for a single man and NZ\$800 for a married man can be claimed to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, SW1Y 4TQ, with whom applications will close on 22 August 1974.

Please quote reference P/T 108 when enquiring.

(277)

Immunology Research

G. D. Searle are one of the world's leaders in medical research. A vacancy has arisen in the Research Division based at High Wycombe for a Technician/Research Assistant to join a group working on the experimental aspects of tumour immunology.

The position will probably suit someone with laboratory experience in the field of immunology, but recent graduates in biological science who are interested in this area of work should also apply. In addition to an attractive commencing salary, company

benefits include a contributory Pension Fund, BUPA Scheme, excellent canteen and an active sports and social club. If necessary, assistance with relocation expenses will be given in appropriate circumstances. Please apply to H. W. Cooke, Personnel Manager, Research and Development Division, G. D. Searle & Co. Ltd., Lane End Road, High Wycombe, Bucks, or telephone him on High Wycombe 21124 ext. 130 quoting reference IR/113.

SEARLE

(279)

TECHNICAL DEVELOPMENT MANAGER HIGH VACUUM TECHNOLOGY

A Physics Graduate, aged about 40, is required to head a technical group engaged in high voltage, high vacuum technology.

The Group will evaluate developments and as appropriate will introduce innovations to manufacturing processes which have, in part, being current for some 25 years. The Manager may initially secure a detailed appreciation of the problem areas through secondment for a period of six months to an associated U.S. Company.

This is a challenging appointment, and

there are opportunities for further advancement within the organisation. Location is North West London.

Please reply giving full personal and career details to Position Number BKT 4495 Austin Knight Limited, London, W1A 1DS.

Applications are forwarded to the client concerned, therefore companies in which you are not interested should be listed in a covering letter to the Position Number Supervisor.

(321)

MANCHESTER AREA HEALTH AUTHORITY (TEACHING)
SOUTH DISTRICT, WITHINGTON HOSPITAL
MANCHESTER M20 8LR

The National Reference Laboratory for Anticoagulant Control Reagents

MEDICAL LABORATORY TECHNICIAN

required. A.I.M.L.T. qualifications or good honours degree in applied science necessary. Appointee will be trained in basic routine blood coagulation procedure and will participate in routine work, research and development. Good career prospects.

Applications including names of two referees to the Hospital Secretary quoting reference B29. (343)

ROYAL PERTH HOSPITAL (WESTERN AUSTRALIA)

Applications are invited for the position of:
**SENIOR TECHNOLOGIST
(ELECTRON MICROSCOPY)**

Applicants should possess an appropriate qualification such as A.A.I.M.T., F.A.I.M.T., B.Sc., B. App.Sc. (M.T.) or equivalent, and should be experienced in both Transmission and Scanning Microscopy techniques and equipment.

Supplementary trading at the manufacturer's works in Germany or America may be offered according to the needs of the appointee.

The appointee will be responsible for the technical development and function of the newly established Electron Microscopy Unit at this 1,004 bed General Hospital.

Duties will involve the preparation, examination and photomicrography of predominantly biological specimens in collaboration with various hospital departments; instruction and supervision of technical staff; adjustment and maintenance of equipment; records, filing etc.. Salary range \$A10,039 to \$A11,033 per annum.

Further information is available on request.

Applications stating name, age, qualifications, experience, Ref. No. 140a, together with names and addresses of three referees and accompanied by a recent photograph should reach the Administrator by August 19, 1974.

Box X 2213, GPO, Perth, Western Australia, 6001. (319)

MAX-PLANCK INSTITUT FÜR MOLEKULARE GENETIK

BERLIN (WEST)

has openings for

QUALIFIED TECHNICIANS

to aid with research in the following areas: electron microscopy, microbial genetics, biochemistry of microorganisms, biochemistry of nucleic acids. Salary according to age and experience between DM 19,000 and 24,000 p.a. Travel expenses to Berlin after employment can be met. Speaking knowledge of German would be helpful but not required in the laboratory. Applications giving names of two referees should be sent to:

Professor T. A. Trautner
Max-Planck-Institut für molekulare Genetik
D-1000 Berlin 33
Innestrasse 63/73 (316)

UNIVERSITY OF NATAL DEPARTMENT OF CHEMISTRY PIETERMARITZBURG

Applications are invited from suitably qualified persons for the appointment to the post of

JUNIOR LECTURER IN CHEMISTRY

The salary scale attached to the post is R3 600 by 150 to R4 500 plus a 15% pensionable allowance. The position is tenable for three years in the first instance.

The duties are teaching and research in Organic Chemistry. The post is suitable for a person with a B.Sc.(Hons.) or higher degree. The research will be in the field of insulin chemistry.

Application forms are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, 4001, Natal, South Africa, with whom applications on the prescribed form should be lodged not later than August 31, 1974, quoting Ref. Adv. 78/74.

Further particulars are obtainable from Professor D. A. Sutton, Head of the Department of Chemistry, "Middle Cottage", Sutton End, Crockerton, Warminster, Wiltshire, England, from July 24 to 31, 1974. (296)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF PARASITOLOGY

Applications are invited for the post of Lecturer in the Department of Parasitology. This post is to be filled in January 1975. Candidates should hold a good science degree and doctorate in relevant subjects. Practical experience in the parasitology of tropical diseases is essential and preference will be given to candidates who already have experience in teaching and/or research on parasitic diseases.

The successful applicant may have the opportunity to spend periods of service on secondment overseas at teaching and/or research centres but will be based in the Department of Parasitology.

The initial salary will be within the range £2,118 to £4,896 per annum according to qualifications and experience.

Applications, together with the names of three referees should be received not later than August 15, 1974 by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote ref. RV/N/276127. (270)

ENTOMOLOGIST—**Agrochemical Research**

Fisons Agrochemical Division, one of the major manufacturers of chemicals for crop protection, are expanding their programme of Research and Development. To satisfy part of our needs, we now wish to appoint a Senior Research Assistant in the Biological Screening Department of our Chesterford Park Research Station, near Saffron Walden, Essex.

Ideally, we are seeking either a young graduate in the Biological Sciences, or someone who expects to graduate in 1974, as experience is less important than the ability to fit into an existing team.

As part of that team, the person appointed would be required to carry out insecticide and nematocide screening tests to evaluate the effectiveness of novel compounds, and to assist in the culture of the insect colonies

including the development of methods for new species.

We can offer a competitive starting salary and our other Company conditions of employment are amongst the market leaders.

For further details and an application form, please write, quoting reference 633/to:

Personnel Department,
Fisons Limited—Agrochemical Division,
Chesterford Park Research Station,
Near Saffron Walden,
Essex, CB10 1XL.

(284)

UNIVERSITY OF
NEW SOUTH WALES
SCHOOL OF PHYSICS
LECTURER

High academic qualifications required. Experience in teaching at tertiary level an advantage. Appointment from February 1975.

Salary \$A9,002 range \$A12,352 per annum. Commencing salary according to qualifications and experience.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on **September 13, 1974.** (304)

UNIVERSITY OF QUEENSLAND
Australia
READER IN VETERINARY
ANATOMY

This is the most senior departmental position and it is likely that the successful applicant will rapidly assume the Headship of the Department. Applicants should preferably hold both a veterinary and a higher qualification; they should be able, experienced teachers, with a particular interest in gross anatomy. Research skills, a flair for organisation and originality will all be considered favourably.

The salary is \$A16,389 per annum, and the University provides travelling and removal expenses, superannuation similar to F.S.S.U., housing assistance and study leave.

Additional information and application forms are obtainable from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in London and in Brisbane on **September 30, 1974.** (305)

DALHOUSIE UNIVERSITY
DEPARTMENT OF MICROBIOLOGY

Applications are invited for a Faculty position at the level of **Lecturer/Assistant Professor**. Applicants should have an M.D. or Ph.D. with research experience and a major interest in medical microbiology. Salary according to qualifications and experience.

Applications including Curriculum Vitae and the names of three referees to:

Dr K. R. Rozee,
Department of Microbiology
Dalhousie University
Halifax, Nova Scotia, Canada.

(307)

Glaxo

GLAXO LABORATORIES LIMITED

Fermentation Microbiologist

Ulverston, Cumbria

We require an experienced microbial physiologist to join our Fermentation Development Department. The department consists of microbiologists, biochemists, geneticists and chemical engineers in multi-disciplinary project teams. Each team is responsible for the R & D in one of our major product areas, which includes antibiotics, vitamin B12 and industrial enzymes. The successful candidate would be appointed as a member of a team, seniority depending on his or her proven ability and experience.

The job involves the origination and execution of experimental programmes from the laboratory to the production scale. Although experience of strain selection and the biosynthesis of extracellular products would be an advantage, the main qualities we are looking for are an understanding of the physiology of microbial growth and product formation and experience in the use of fermenters.

Ideally candidates should have some postgraduate experience either in academic or industrial research. The salary will be according to age and experience.

The factory is one of the largest fermentation factories in the world. Ulverston is a pleasant market town situated on the southern fringe of the Lake District National Park. Relocation expenses will be reimbursed where appropriate.

Applications in writing to:

**The Senior Personnel Officer (EWM), Glaxo Laboratories Limited,
North Lonsdale Road, Ulverston, Cumbria, LA12 9DR.**

(322)

Republic of South Africa

PROVINCIAL ADMINISTRATION OF THE CAPE OF GOOD HOPE

Hospitals Department

Principal Professional Officer (Medical Biochemist)

The successful applicant will hold a responsible position in diagnostic Chemical Pathology at the Groote Schuur Hospital and other associated Teaching Hospitals in the environment of Cape Town.

Essential requirements are a Bachelor's degree, Honours degree, or a Master's degree plus 3, 2 or 1 years' training as a Professional Officer, respectively. Additionally, a Ph.D in Medical Bio-Chemistry or Chemical Pathology will be a strong recommendation. A medical qualification is not a necessity.

Salary will be in the range £4523 x £188 — £5089, approximately. In addition, a pensionable allowance of 15% of basic salary (excluding allowance) is payable as well as an annual vacation savings bonus, subject to certain conditions.

Applications must be made in duplicate on the prescribed form (Staff 23) which is obtainable from the Chief Migration Officer, South African Embassy, Trafalgar Square, London WC2N 5DP and should be forwarded, by airmail, to the Director of Hospital Services, PO Box 2060, Cape Town 8000, South Africa, as soon as possible.

CHROMATOGRAPHY SPECIALIST

The role of the Analytical Chemistry Department within the Central Research Division is to devise and develop methods to control potential new drugs from the discovery to marketing phase. A principal aim is the generation of technical data for submissions to world-wide regulatory agencies.

To maintain the technical support currently required, we now need an additional graduate Chemist to work as a Chromatography Specialist. The work of the Analytical Chemistry Department is varied and includes the application of GLC, HPLC and TLC to a wide variety of problems including homogeneity assessment, the quantitative control of impurities and stability studies. The job involves working with a large number of Research Staff and provides an excellent opportunity to gain a wide experience of

separation science in a pharmaceutical research environment.

The successful applicant will have a BSc or GRIC qualification plus up to four years industrial experience in one or more branches of Chromatography. He/she will have a keen interest in the qualitative and quantitative analysis of mixtures of organic compounds. A knowledge of other instrumental techniques will be an added recommendation.

Our laboratories are situated in a pleasant rural/coastal area at Sandwich, Kent.

Our conditions of employment include a free pension and death benefit scheme, assistance with removal costs (where appropriate), bonus and flexible working hours.

Pfizer

Applications, giving brief details of age and experience should be addressed to:—

D. W. Sells
Personnel Manager
Central Research
Pfizer Limited
Sandwich
Kent

(300)

Agricultural Research Council UNIT OF MUSCLE MECHANISMS AND INSECT PHYSIOLOGY OXFORD

This Unit is investigating the molecular mechanism of muscular contraction and requires:

1) **RESEARCH ASSISTANT**
with degree in physics or chemistry for research programme involving measurements of electrical conductivity

2) **SCIENTIFIC OFFICER**
with qualification in entomology and practical ability to supervise colonies of unusual tropical insects

3) **RESEARCH TECHNICIAN**
for work on protein biochemistry

4) **RESEARCH STUDENTS**
with good degree in biochemistry or physical sciences for research on contractile systems

Further details from Professor J. W. S. Pringle,
Department of Zoology, Oxford OX1 3PS.

(310)

UNIVERSITY OF WATERLOO DEPARTMENT OF APPLIED MATHEMATICS

invites applications from candidates qualified for a position at the

ASSISTANT OR ASSOCIATE PROFESSOR

level with research interests in the area of Partial Differential Equations. Candidates will be expected to have at least three years post Ph.D. experience and a background in applied mathematics. The lecturing load is not heavy but considerable emphasis will be placed on teaching ability. Present minimum salary for Assistant Professors is \$13,000 and for Associate Professors is \$17,000. Closing date for applications November 30, 1974. Starting date to be arranged but not later than July 1, 1975. Send curriculum vitae, details of research and teaching experience and names of three referees to Dr D. G. Wertheim, Chairman, Department of Applied Mathematics, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1.

(311)

IRELAND

(a) SENIOR GEOLOGISTS (5) (b) GEOLOGISTS (II)

required in the Geological Survey.

The Government is continuing the implementation of its programme for the modernisation and expansion of the Geological Survey of Ireland to ensure that it is able to contribute in full to the economic development of the country.

The present recruitment is in the second phase of expansion which includes the provision of additional office and laboratory accommodation and the necessary modern equipment.

It is proposed to continue the re-mapping of the entire area of the Republic and to carry out the necessary regional studies both onshore and offshore. Applied research projects are also being undertaken to improve prospecting and mapping methods in Ireland.

It is hoped to assemble a team of earth scientists of high calibre who will have a practical bias and who will be given every encouragement to carry out applied research and to publish the results.

Senior Geologist:—There is one vacancy in each of the following fields:—

Economic Geology, Marine Geology, Palaeontology, Engineering Geology, Hydrogeology. Applicants must hold a PhD and have had at least 6 years relevant experience *or* hold a 1st or 2nd Class Honours degree and have had at least 8 years relevant experience and be under 50 years of age.

Commencing salary up to £3952 (man) or £3359 (women) possible
Maximum £4095 (Man) £3481 (Woman)

Geologist: There are 11 vacancies.

Applicants must hold a 1st or 2nd Class Honours Degree in Geology *or* in Geography with Geomorphology as a major subject and be under 40 years of age. One of the appointees must have experience in mineral resources, data collection and prospecting, one must have training in hydrogeology and a knowledge of water supply problems and one must have a knowledge of geochemical techniques.

Commencing salary up to £3041 (Man) or £2699 (Woman) possible
Maximum £3736 (Man) £3183 (Woman)

Non-contributory pension scheme and contributory Widows and Orphans pension scheme apply to all appointees.

Application forms, and further details of these posts may be obtained from the Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin 1.

CLOSING DATE: 15th AUGUST 1974

(342)

CSIRO AUSTRALIA

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

RESEARCH SCIENTIST DIVISION OF ANIMAL HEALTH

Melbourne, Victoria

FIELD

MICROBIOLOGICAL SECURITY

LOCATION: The position is initially located at the CSIRO, East Melbourne, but some time will be spent at other locations in Melbourne. After a period of 5–6 years the position will be transferred to the Animal Health Laboratory at Geelong, Victoria.

GENERAL: A major biological laboratory for the diagnosis of and research on exotic and indigenous diseases of livestock will be built in Geelong. The microbiological performance of the facilities of great importance and will be the responsibility of the Officer-in-Charge of the Laboratory. The successful applicant will be working closely with and be responsible to the Officer-in-Charge.

DUTIES: Research into the behaviour of micro-organisms in non-biological environments and specifically into engineering, mechanical, hydraulic and chemical systems for handling these agents.

QUALIFICATIONS: A Ph.D. degree in microbiology or equivalent qualifications; extensive experience in the achievement, maintenance and control of microbiological security, with demonstrable research ability.

SALARY: Appointment will be made within the salary ranges of Senior Research Scientist or Principal Research Scientist \$A12,674—\$A17,549 p.a.

TENURE: The position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications stating full personal and professional particulars, the names of at least two professional referees and quoting Reference Number 201/455, should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64–78, Kingsway,
LONDON, WC2B 6BD.
by the 16th August, 1974

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

(346)

SHEFFIELD AREA HEALTH AUTHORITY (TEACHING)

Sheffield Central District (Teaching) NON-MEDICAL SCIENTIFIC OFFICER

required until October, 1975, to take part in a research project investigating into the Excretion of Sulphated Corticosteroids in Breast Cancer.

Applicants should possess a first or second class Honours degree. Whitley Council Terms and Conditions of Service apply. Salary: £1,797 rising to £2,259 p.a.

Applications stating age, qualifications, experience and the names and addresses of two referees to the District Administrator, Sheffield Area Health Authority (Teaching), Central District (T), 10 Beech Hill Road, Sheffield S10 2RZ, by August 3, 1974. Further details supplied on request.

(376)

Fermentation Technologist CAWTHORN INSTITUTE NELSON NEW ZEALAND

Application are invited for the position of **FERMENTATION TECHNOLOGIST** in the Research Section of the Cawthorn Institute. University degrees are not a prime consideration.

A proven record of accomplishment in carrying out both batch and continuous fermentations is required. Skill in assembling and operating modern control equipment for pH control, dissolved oxygen control, etc. is essential.

A new and well equipped laboratory is available for this work.

Salary will be commensurate with qualifications and experience within the range of \$6,000 to \$9,000 N.Z. a year.

Nelson combines a relatively small community with a very favourable climate and ready access to three National Parks and many recreations eg. swimming, boating, tramping, skiing, climbing, fishing, shooting.

Please submit applications with full details of educational and experience qualifications and the names of at least 2 referees to the Director, P.O. Box 175, Nelson, New Zealand by August 1, 1974. (317)

MOLECULAR BIOLOGIST

Faculty position for Ph.D. molecular biologist, 2 or more years of experience desirable. Position involves collaborative research on herpesviruses and oncornaviruses with light teaching responsibility to medical and graduate students. Send applications and curriculum vitae to Dr Meihan Nonoyama, Department of Microbiology, Rush Medical College, 1753 West Congress Parkway, Chicago, Illinois, U.S.A. 60612. An equal opportunity employer. (318)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF BOTANY AND MICROBIOLOGY

Applications invited for the post of postdoctoral **RESEARCH ASSISTANT** in the Department of Botany and Microbiology, to work on the differentiation and ultrastructure of spermatozoid nuclei. Familiarity with the basic techniques of light and electron microscopy is essential, and some experience of fluorescence microscopy and autoradiography would be desirable. Applications, giving the names of two referees, to Assistant Secretary (Personnel) University College London, Gower St. London WC1E 6RT. (323)

UNIVERSITY OF BRADFORD POSTGRADUATE SCHOOL OF STUDIES IN BIOLOGICAL SCIENCES

Applications are invited from graduates in biochemistry, biology or suitable related subjects for a research assistant to work on the carbohydrate of x-lactalbumin and their role in lactose synthetase activity. The appointment is for a period of one year and the successful applicant will have the opportunity of registering for an MSc. Informal interview can be arranged by contacting Dr J. V. Wheelock, Tel. No. Bradford 33466, Ext. 579. Further particulars and application forms from the Registrar, University of Bradford, Bradford, BD7 1DP. (291)

Histology Technician

required in the Department of Neurology to take charge of nerve and muscle biopsy work. Applicants must be state registered and have had a minimum of 3 years experience in basic histological techniques. Experience in electron microscopy an advantage, but not essential. Salary scale £1,566 to £2,418.

Job description and application form (to be returned by July 31), from Personnel Officer, The Royal Free Hospital, 21 Pond Street, Hampstead NW3 2PN. Tel: 01-794 0431 Ext. 12. (320)

UNIVERSITY OF RIYADH
MEDICAL SCHOOL

Saudi Arabia

(in association with the University of London)

Applications are invited from male candidates only for the following posts in the Medical School at the University of Riyadh. The vacancies have arisen as a result of the rapid expansion of the School.

TECHNICIAN IN CHEMISTRY
TECHNICIAN IN BIOLOGY
TECHNICIAN IN HISTOLOGY
TECHNICIAN IN ELECTRONIC
PHYSIOLOGY
TECHNICIAN IN PATHOLOGY
TECHNICIAN IN PHARMACOLOGY

Successful candidates will possess an O.N.C., City and Guild certificate or equivalent qualification and considerable experience.

The University of Riyadh is an independent University established in 1957. In 1968 the University established a Medical School in association with the University of London. The request by the University of Riyadh for assistance in this project is covered by a sponsorship agreement. The University of London advises on the curriculum, the form and conduct of examinations, the physical facilities for teaching, the appointment of academic staff and other matters. From the outset it has been anticipated that this assistance would continue over a period of at least 10 years possibly extending to 15 years. All teaching of medical undergraduates is in the English language.

Appointments are for 1 year or longer; renewable. Secondments would be considered.

Salary will be negotiable in accordance with qualifications and experience. An attractive housing allowance will be granted.

Detailed applications (three copies) including a curriculum vitae and naming three referees should be sent not later than July 26 to the Inter-University Council for Higher Education Overseas, 90-91 Tottenham Court Road, London, W1P 0DT from whom further particulars are available.

(336)

IMPERIAL COLLEGE
DEPARTMENT OF BIOCHEMISTRY**Microbial
Biochemist**

Applications are invited for a S.R.C. Postdoctoral Assistantship for work on the Biosynthesis of Ergot Alkaloids in collaboration with Dr P. G. Mantle and Dr G. Mellows.

Candidates should have research experience in Microbial Biochemistry. Experience in the culture of Filamentous Fungi and in Biosynthetic Techniques would be an advantage.

The appointment is tenable for two years, commencing October 1, 1974. Salary range £2,118 to £2,247 p.a. plus £162 London Allowance (under review) (with F.S.S.U.).

Applications, including curriculum vitae and the names of two referees should be sent as soon as possible to either Dr P. G. Mantle or Dr G. Mellows, Department of Biochemistry, Imperial College, London SW7 2AZ.

(337)

POSTDOCTORAL BIOCHEMIST

required with experience in enzymology to investigate certain aspects of immunology in dermatology in the dermatology laboratories at St Helier Hospital. The post is for a period of three years in the first instance on a Senior Biochemist grade. Subject to Whitley Council conditions of service. Salary £2,964 to £3,843 plus London Weighting, depending on experience. Other staff in the laboratory include a graduate research worker and a research registrar. Further information may be obtained from Dr E. L. Rhodes, St Helier Hospital, Carshalton, Surrey. Closing date for receipt of applications September 1.

(338)

**CSIRO
AUSTRALIA****APPOINTMENT OF
RESEARCH SCIENTIST**DIVISION OF PLANT INDUSTRY
CANBERRA A.C.T.

FIELD:

**MOLECULAR
GENETICS**

GENERAL: The Organisation's Division of Plant Industry, with Headquarters situated in Canberra, A.C.T., has a staff of 120 scientists, conducting pure and applied research in genetics, plant breeding, biochemistry, physiology, microbiology, mineral nutrition, ecology, crop adaptation and plant introduction. It is well equipped with instruments for the characterisation of macromolecules.

The Genetics Group consists of 13 Research Scientists. The work in progress includes the study of chromosome structure and replication, the evolution of enzymes and the genetic mapping of enzyme structure, molecular mechanisms of mutation and adaptation and the genetics of regulatory processes.

DUTIES: To participate in a research programme concerned with studies of the molecular structure and function of eukaryote chromosomes.

QUALIFICATIONS: Applicants should have a Ph.D. degree in an appropriate field or postgraduate research experience of equivalent standard or duration supported by satisfactory evidence of research ability.

SALARY: The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A9,698 to \$A14,706 p.a. In addition to salary, a reasonable rental subsidy on furnished accommodation may be paid to a married male appointee.

TENURE: The duration of the appointment will be for a fixed term of either two or three years, after which, if mutually desired, either an extension of tenure or appointment for an indefinite period will be considered. An indefinite appointment carries Australian Government Superannuation benefit.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 130/1270 should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway,
LONDON WC2B 6BD

by August 9, 1974.

Applications in U.S.A. and Canada should be sent to:
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

(351)

UNIVERSITY OF MELBOURNE
LECTURESHIP (LIMITED TENURE)

in the

DEPARTMENT OF MATHEMATICS

Applications are invited for this position, which is for a Limited Tenure period of 3 years. The starting date is January 1, 1975, or as soon as possible thereafter. Preference will be given to applicants whose field of interest is analysis, algebra, topology or some other branch of pure mathematics.

Salary: A\$9,002 to A\$12,352 per annum. Initial salary will be in the range depending on qualifications and experience.

Further information, including conditions of appointment, is available from The Registrar. All correspondence should be addressed to The Registrar, referring to Position No. 618033, University of Melbourne, Parkville, Victoria, 3052, Australia. Applications close on August 23, 1974.

(347)

PUBLIC HEALTH LABORATORY
SERVICE

LEEDS REGIONAL LABORATORY

Vacancies for

SCIENCE GRADUATES

Applications are invited from science graduates with Class I or II honours degrees in microbiology.

One post is in general microbiology including reference, hospital and public health work and one is particularly in the microbiology of food, milk, water and the environment.

Initial appointment will be to the Senior or Basic Grade, depending on qualifications and experience. N.H.S. terms and conditions of service.

Applications, including the names of two referees to the Director, Leeds Regional Public Health Laboratory, Bridle Path, York Road, Leeds LS15 7TR, by August 15, 1974.

(361)

SOUTH AFRICAN SUGAR ASSOCIATION
EXPERIMENT STATION
MOUNT EDGECOMBE, NATAL
REPUBLIC OF SOUTH AFRICA

CHIEF RESEARCH OFFICER

The Experiment Station of the South African Sugar Association at Mount Edgecombe, Natal, requires the services of a Chief Research Officer. The successful applicant will be responsible to the Director for the operations of the following departments: Agricultural Engineering; Agronomy; Biometry; Chemistry and Soils; Entomology and Nematology; and Land and Water Management. His duties will include the preparation and supervision of annual programmes of work, the administration of a specialist advisory service to all sugarcane growers and the motivation and co-ordination of special research projects. Applicants should preferably hold a Ph.D. or an equivalent degree in science or agriculture. Extensive experience in research will be an essential pre-requisite.

This appointment holds good prospects for an outstanding scientist with organizing ability. It will also include opportunities for overseas travel when visits to other institutes are warranted.

Salary will be commensurate with qualifications, experience and the senior grading of the appointment.

Application forms, a list of benefits (which include a 10% annual bonus) and conditions of service are obtainable from:

South African Sugar Association,
Fountain House,
125-135 Fenchurch Street,
London,
England EC3M 5EH.

Completed forms, together with curriculum vitae, should be air-mailed directly to:

The Director,
S.A.S.A. Experiment Station,
P.O. Mount Edgecombe, 4300,
Natal,
Republic of South Africa.

(332)

ROYAL MARSDEN HOSPITAL
SUTTON, SURREY

Pharmaceutical Scientist

Graduate scientist, required for responsible position in radioisotope section of Physics Department. Experience with radioactive materials or qualification in pharmacy essential. Duties involve all aspects of preparation, dispensing and testing of radiopharmaceuticals used mainly by a large Nuclear Medicine Department. Participation in development of new radiopharmaceuticals and techniques will also be expected. Salary and grading will depend on qualifications and experience but is expected to be in range approximately £2,000 to £3,000 per annum.

Application forms and further information can be obtained from The Administrator, Royal Marsden Hospital, Downs Road, Sutton, Surrey. (01-642 6011 Ext. 201). (339)

INSTITUTE OF NEUROLOGY

requires TECHNICIAN to assist in Muscular Dystrophy Dept. in biochemical studies of muscle. Qualifications: H.N.C. preferable but not essential. Salary: University scale from £1,440 to £1,845 plus £126 L.A. Applications in writing giving qualifications, experience and names of two referees to: Dr R. Yasin, Muscular Dystrophy Research Laboratories, National Hospital, Queen Square, London WC1N 5BG. (333)

UNIVERSITY OF OXFORD NUFFIELD INSTITUTE FOR MEDICAL RESEARCH

Applications are invited for a Graduate Research Assistant to participate in a programme of research (supported by the M.R.C.) into the regulation of glucagon and insulin release in foetal and newborn lambs. Applicants should have a Ph.D. or an honours degree in biochemistry and physiology with some postgraduate experience. Experience in radio-immunoassay techniques or foetal studies is desirable. The post would be for a period of two years. Salary in the range £1,833 to £2,580 p.a. Applications, together with a curriculum vitae and the names of two referees should be sent to Dr J. M. Bassett, Nuffield Institute for Medical Research, Headley Way, Headington, Oxford OX3 9DS. (367)

INSTITUTE OF ORTHOPAEDICS

(University of London)

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL
Brockley Hill, Stanmore, Middlesex HA7 4LP

Applications are invited for the post of

Lecturer in Cell Science

within the Professorial Research Unit of the Institute.

Applicants should preferably have a higher degree, some experience in electron microscopy and an interest in cell biology. This post, which is renewable annually for the first three years, will carry a salary within the Lecturer scale £2,118 to £4,896 plus £213 London Allowance; F.S.S.U. superannuation. Placing on the scale will be according to qualifications and experience. Further details may be obtained from Dr M. W. Elves, Professorial Research Unit, Stanmore.

Applications, together with names of three referees, should be received by the Secretary, Institute of Orthopaedics, 234 Great Portland Street, London W1N 6AD, not later than August 30, 1974.

(365)

THE QUEEN'S UNIVERSITY OF BELFAST

Research Assistant

Applications are invited from graduates in botany, biochemistry or biology for an S.R.C. research assistantship in the Department of Botany to work on the proteins and lipids of envelope membranes of differentiating chloroplasts. The post is tenable initially for a period of one year, but it may be renewed for a further period of two years.

The salary scale is £1,239 to £1,818; initial placing on this scale will depend on age and qualifications.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, Belfast BT7 1NN, Northern Ireland. (Please quote Ref. 74/N).

Applications, giving names and addresses of two referees, should be received by August 23, 1974. (349)

**PARKINSON'S DISEASE SOCIETY
OF THE U.K. LTD.
RESEARCH FELLOWSHIP**

Applications are invited for the appointment of a full-time **RESEARCH FELLOW** into subjects related to the cause and treatment of parkinsonism. The work must be conducted at a recognised institution and the tenure of support will be one year in the first instance renewable for a maximum of three years. Salary will be determined according to seniority and experience. Application forms are not issued but applicants are invited to write to The Executive Director, Parkinson's Disease Society, 81 Queens Road, London SW19 8NR giving curriculum vitae, proposed place of work, subject of research and tenure of grant and names of two or three referees. (356)

**CHAIRMAN
UNIVERSITY OF CALIFORNIA
SCHOOL OF MEDICINE**

Applications are invited for the position of Chairman, Department of Human Anatomy, University of California School of Medicine, Davis.

We are seeking applicants with an active interest in teaching and research. Successful applicant will assume leadership in the department's rôle in an integrated medical school curriculum and in graduate training. Send resumé and references to Dr Edwin G. Krebs, Chairman of Search Committee, Department of Biological Chemistry, School of Medicine, University of California, Davis, Ca. 95616. An affirmative Action-Equal Opportunity Employer. (357)

THE UNIVERSITY OF ADELAIDE

proposes to appoint one or more

DEPUTY VICE-CHANCELLORS

from the beginning of 1975.

Persons with appropriate academic and/or administrative qualifications and experience who may be interested in such an appointment are invited to write as soon as possible, in confidence, to the Vice-Chancellor, the University of Adelaide, G.P.O. Box 498, Adelaide 5001, South Australia, from whom further information may be obtained.

The Calendar of the University may be seen in the office of the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF, or in the library of any university that is a member of the Association. An outline description of the University may be found in the A.C.U. Yearbook, which is similarly available. (358)

**UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF EXPERIMENTAL
PATHOLOGY
GRADUATE BIOCHEMIST**

required for M.R.C. supported project on Characterisation of urokinase. Two year appointment from October 1, 1974.

Salary according to age, qualification and experience in the range either for Research Assistants (if no previous experience) £990 to £1,404, or for Research Associates £1,758 to £2,404 plus F.S.S.U.

Further particulars from Dr P. Wolf, Department of Experimental Pathology (Rheumatism Research Wing), the Medical School, University of Birmingham, Birmingham B15 2TJ, to whom applications (six copies) naming two referees should be sent by August 10, 1974. (363)

**UNIVERSITY COLLEGE GALWAY
DEPARTMENT OF MICROBIOLOGY
RESEARCH ASSISTANT**

Applications are invited for the post of post-graduate research assistant to participate in a Euratom sponsored project on the effects of radiation on blue-green algae. Candidate should be qualified in Microbiology or Genetics or a related field. Full particulars from Dr J. A. Houghton, Department of Microbiology, University College, Galway, Ireland. (369)

**UNIVERSITY OF ABERDEEN
DEPARTMENT OF BIOCHEMISTRY**

A postdoctoral research assistant with experience of enzyme isolation is required to work under the direction of Dr J. Jeffery on the isolation and study of certain dehydrogenases. Initial appointment for one year at a salary of about £2,000 per annum, depending on experience.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by August 31, 1974. (374)

University of Amsterdam

In the Chemistry Subfaculty a position is available for a

**(senior) lecturer
(wetenschappelijk
(hoofd) medewerker)**

within the group Separation Methods of the Department of Analytical Chemistry. This group works on chromatographic methods of separation, especially on advanced (high) pressure liquid chromatography.

The applicant is expected after some time to make an active contribution to the further development of this field of chromatography and he (she) is expected to guide scientific research of doctoral candidates and students and to partake in instruction.

Applications in writing within 3 weeks after publication are to be addressed under number 74-1 to

Prof. Dr. J. A. A. Ketelaar, chairman of the nomination committee, Laboratory for Electrochemistry, Nieuwe Achtergracht 166, Amsterdam-C., Netherlands.

Information can be obtained from Dr. H. Poppe, of the Department of Analytical Chemistry, Nieuwe Achtergracht 166, Amsterdam. (Tel. (020) 522.3540).

(309)

**FLINDERS UNIVERSITY OF SOUTH AUSTRALIA
SCHOOL OF MEDICINE
LECTURERS, SENIOR DEMONSTRATORS AND DEMONSTRATORS
IN CLINICAL BIOCHEMISTRY, HUMAN MORPHOLOGY
AND HUMAN PHYSIOLOGY**

Applications are invited for lectureships and demonstratorships in the new School of Medicine currently being established in Adelaide at the Flinders University of South Australia in each of the following fields: Clinical Biochemistry, Human Morphology and Human Physiology.

The School of Medicine will form an integral part of the Flinders Medical Centre, a 710 bed teaching hospital located on campus. The first medical students began their course this year and will enter the Centre in February 1975. It is hoped that appointees will take up their positions by October 1974 in order to help plan the integrated curriculum.

Suitably qualified appointees will have responsibility in the areas of teaching, research and clinical service. Lecturers with medical qualifications registrable in South Australia will receive a clinical loading, the amount depending on their qualifications and the degree of clinical responsibility undertaken. Conditions of service include provision for transportation expenses, superannuation tenure, study and long service leave.

Present salary scales are: Lecturer \$A8,698 to \$A11,982; Senior Demonstrator \$A7,270 to \$A8,698; Demonstrator \$A5,332 to \$A7,015.

Further information may be obtained from the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications should be lodged with the Registrar, The Flinders University of South Australia, Bedford Park, South Australia, 5042, by August 16, 1974. (379)

EXPERIENCED PHARMACOLOGIST? PHYSIOLOGIST? BIOCHEMIST?

...lead a team with ICI

ICI Pharmaceuticals Division seek an experienced Pharmacologist, Physiologist or Biochemist with training or interest in gastroenterology to lead a biological team in a multi-disciplinary group concerned with therapy for peptic ulcer disease. It is envisaged that the work will involve fundamental research into factors influencing gastric secretion mucosal 'barrier'.

This is a challenging opportunity to work in modern well-equipped laboratories situated in rural North Cheshire but within easy reach of Manchester and other important centres in the area. The area offers a good range of houses suitable for most price ranges.

Write, giving brief details of experience and qualifications, to:

M. F. Losse, Personnel Department, Imperial Chemical Industries Limited, Pharmaceuticals Division, Mereside, Alderley Park, Nr. Macclesfield, Cheshire.

**Pharmaceuticals
Division**

(378)

LEICESTERSHIRE AREA HEALTH AUTHORITY (T) AREA MEDICAL PHYSICS DEPARTMENT

Applications are invited from Graduates for three newly established posts in the Leicestershire Medical Physics Department. This department, which is undergoing considerable expansion, provides a service for the hospitals in the Leicester Area.

PHYSICIST SENIOR OR BASIC GRADE

Physicist is required with experience of Physiological Measurement. The successful applicant will be expected to become involved in various aspects of medical measurement. Within a developing medical school, these will initially include the measurement of blood flow and pressure, particularly in the limbs. Isotope work will also be undertaken at a later stage. The successful candidate should be prepared to become involved in both developmental and routine aspects of this programme.

ELECTRONIC ENGINEER or PHYSICIST SENIOR OR BASIC GRADE

A vacancy exists for an experienced Physicist or Electronic Engineer to set up an Audiological testing section involving clinical work.

This post will provide scope for developmental work in which the successful applicant will be encouraged to participate. Opportunities will occur for him to be engaged also in other aspects of Medical Physics at the Leicester Royal Infirmary. Applicants should have a good honours degree in electronic engineering or physics with a special interest in electronics and experience in this field would be desirable, though not essential.

PHYSICIST BASIC GRADE

Applications are invited for the post of basic grade physicist in the Leicestershire Area Medical Physics Department. The successful candidate will participate in all aspects of the work of the department including Nuclear Medicine, Radiotherapy, Electronics and Instrumentation. This post would be suitable for candidates graduating this summer. Candidates should possess a good honours degree in Physics/Electronic Engineering.

Further information from the **Principal Physicist in Charge.**

Applications, etc. to the Secretary, The Leicester Royal Infirmary, Infirmary Square, Leicester. LE1 5WW.

(326)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

Applications are invited from persons with some experience of electron microscopy or graduates considering entering this field for a new appointment of technician in the Department of Histopathology of Charing Cross Hospital Medical School. Duties commencing September/October 1974 will include the maintenance and operation of transmission and scanning electron microscopes. Some initial training will be given which the successful applicant will be encouraged to supplement by external study. Whitley Council terms and conditions of service. Apply to Dr J. G. Jackson, Department of Histopathology, Charing Cross Hospital Medical School, Brandenburgh House, Fulham Palace Road, London W6 9HH. (352)

Guy's Hospital Medical School

Applications are invited for appointment of
JUNIOR LECTURER/LECTURER
in the Department of Microbiology.

Preference will be given to candidates with research experience in the general area of host-microbe interactions or virology.

The Department's interests include pathogenesis and immunology in herpes virus (CMV) infections and cell membrane changes in viral transformation.

Further particulars are available from Professor Mims, Department of Microbiology.

Salary in range £2,553 to £2,787 or £3,012 to £4,668 (both currently under revision) plus superannuation if medically qualified; otherwise £2,580 to £3,285 or £3,285 to £4,896 plus £162 London Allowance and superannuation.

Application forms obtainable from the Dean, Guy's Hospital Medical School, London Bridge SE1 9RT. Closing date August, 21, 1974. (355)

UNIVERSITY OF STIRLING
DEPARTMENT OF BIOLOGY

Research Assistant

Applications are invited for the above S.R.C. financed post to work on carbon metabolism of leaf epidermal tissue with particular reference to stomatal functioning. The appointment is for 3 years with a starting salary of £1,350.

Applications, including the names of two referees, should be sent by August 10, 1974 to Dr C. M. Willmer, Department of Biology, University of Stirling, Stirling. (370)

NEW ZEALAND
UNIVERSITY OF CANTERBURY
CHRISTCHURCH

The Council of the University invites applications for the following vacancy:

**SENIOR LECTURER or
LECTURER IN ASTRONOMY**

Applicants must have a strong interest in the fundamental physical processes of importance in Astronomy, so that they are capable of teaching not only in Astronomy but also in Physics courses.

The salary for Lecturers is on a scale from NZ\$7,361 to NZ\$9,339 per annum; for Senior Lecturers NZ\$9,503 to NZ\$11,153 (bar) NZ\$11,484 to NZ\$12,142 per annum.

Particulars, including information on travel and removal allowances, study leave, housing and superannuation may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close on **August 31, 1974.** (371)

UNIVERSITY OF EDINBURGH
LECTURESHIP IN APPLIED
GEOLOGY

Applications are invited for the post of Lecturer in Applied Geology. Candidates should be experienced in some aspect of Applied Geology, for example, fossil fuels.

Salary scale is £2,118 to £4,896 per annum. Superannuation under F.S.S.U.

The successful candidate will be expected to take up the post on October 1, 1974 or as soon thereafter as may be mutually convenient.

Applications (six copies) should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL by August 31, 1974. Please quote reference number 1034. (372)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF GEOLOGY
UNIVERSITY DEMONSTRATOR
IN OCEANOGRAPHY

Applications are invited for the post of University Demonstrator in Oceanography. Candidates, preferably, should have experience in the field of Marine Chemistry.

Salary scale is £1,848 to £2,538. Superannuation under F.S.S.U.

The successful candidate will be required to take up his or her post on October 1, 1974 or as soon thereafter as may be mutually convenient.

Applications (three copies) should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL by August 31, 1974. Please quote reference number 7007. (373)

TECHNICIAN for POLIO UNIT

Technician required for work involving safety and animal testing of human vaccines at a small unit based at Mill Hill, N.W.7.

Duties consist of preparation of equipment and care of laboratories, clinical examinations, some post mortem work and preparation of pathological tissues. The successful candidate, whilst having practical bias, would be involved in the research work carried out by the scientist. Relevant laboratory experience would be an advantage. He or she should hold at least a relevant H.N.D. or H.N.C.

Salary: On the Technician scale £1,566 to £2,418 per annum, depending upon experience. (Salary award pending).

be addressed to Robin Dunn, Personnel Officer, National Institute for Biological Standards and Control, Holly Hill, Hampstead, London NW3 6RB. Tel: 01-435 2232. Applications quoting reference 0021 should (350)

NIBSC

National Institute for Biological Standards and Control

Reckitt & Colman

PHARMACEUTICAL DIVISION

Psychopharmacological Research

Applications are invited from graduates with 2 or 3 years experience in CNS research or from candidates completing a Ph.D. in psychopharmacology.

The successful candidate will be engaged in the evaluation of the actions of psychotropic drugs on animal behaviour, particularly rodent operant behaviour, and in innovative experimental work.

Reckitt and Colman operates internationally and its pharmaceutical interests are based at Hull where first class facilities are available. Over the next few years major investment is planned in an expansion of the Company's pharmaceutical research activities.

Salary is negotiable according to experience and qualifications. Fringe benefits include annual bonus and relocation assistance.

Please write quoting ref. U.85 and giving relevant details of experience and qualifications to: **R. A. Sandow, Divisional Personnel Manager, Pharmaceutical Division, Reckitt & Colman, Dansom Lane, Hull HU8 7DS.**

(359)

Food Research

H. J. Heinz Company Limited require a Technical Assistant to work in their Food Research Department situated in the company's modern headquarters at Hayes Park.

The vacancy will probably be filled by an experienced person, aged 30-50, with a sound technical education to ONC/HNC level.

Primary duties will be concerned with the shelf life assessment of various products, and the observation of changes in the chemical/physical characteristics during storage. Previous experience in the food packaging industry is an obvious advantage. The person appointed to this post will enjoy excellent conditions of work, including a subsidised canteen, annual bonus, staff sales and good pension/free life assurance schemes.

Write in the first instance, giving brief details of career to date to: **I. Wason, HO**
Personnel Services, H. J. Heinz Co. Ltd.,
Hayes Park, Hayes,
Middlesex UB4 8AL.

(377)

Wellcome

Pharmacology Technicians

We have opportunities for Senior and Junior Technicians in our Pharmacology Laboratory. Using modern instrumentation they will work with a team concerned with the discovery and evaluation of new drugs. Candidates should have a keen interest and preferably experience in biochemical or physiology/pharmacology work.

Our laboratories are situated in pleasant parkland surroundings, about 12 miles from Charing Cross, within easy reach of Bromley and Beckenham.

Please write quoting reference U.467 and giving brief details of qualifications and experience to the Personnel Officer,

THE WELLCOME RESEARCH LABORATORIES,
Langley Court,
Beckenham,
Kent BR3 3BS.

(375)

THE CITY UNIVERSITY Department of Chemistry

Applications are invited for a TEMPORARY LECTURESHIP IN PHYSICAL CHEMISTRY

The post will be tenable for up to two years from October 1, 1974 (or as soon as possible thereafter) and will involve both undergraduate teaching and supervision of research students in a group under the general direction of Professor C. F. Cullis. Candidates should preferably have an interest in some branch of chemical kinetics. The salary will be in the range £2,118 to £4,896 per annum plus £213 per annum London Allowance.

For further particulars and application forms please write to the Deputy Academic Registrar, The City University, St. John Street, London EC1V 4PB, quoting reference 143/L/N. The closing date for applications is August 19, 1974. (AK 354)

ROYAL POSTGRADUATE MEDICAL SCHOOL JUNIOR TECHNICIAN/TECHNICIAN

required in Department of Clinical Cardiology. This post will involve dealing with patients and some research work. Qualifications GCE "O" level passes in English, Maths and two Science subjects/ O.N.C. or equivalent. Salary according to qualifications and experience.

Applications to the Secretary, R.P.M.S., Hammersmith Hospital, DuCane Road, London W12 0HS, quoting ref. no. 2/354N. (380)

SUNDERLAND POLYTECHNIC

- a. Lecturer I in Ecology
- b. Lecturer II in Geography

Applications are invited for appointment to the above posts as soon as possible.

For post (a) applicants should have a good honours degree and preferably a higher degree with special interest in aspects of applied Ecology. The successful candidate will be required to contribute to a B.Sc. Environmental Studies degree beginning in September 1974, and to degree and H.N.D. Applied Biology.

For post (b) applicants should have a good honours degree. An interest in planning and other aspects of applied geography would be advantageous. The successful candidate will be required to contribute to a B.Sc. Environmental Studies degree beginning in September 1974, Teachers Certificate, B.Ed., and B.A. Social Sciences degree.

Salary in accordance with Burnham Technical scale, viz:—

Lecturer I: £1,800 to £3,045 (Subject to confirmation);

Lecturer II: £2,700 to £3,474 (Subject to confirmation).

Application form and further particulars may be obtained from: Personnel Officer, Sunderland Polytechnic, Chester Road, Sunderland SR1 3SD, Co. Durham.

Applications should be returned within 14 days of the appearance of this advertisement. (362)

British Museum (Natural History)

Biometrician

- Set up library of computer programs for multivariate analysis and numerical taxonomy ■ Process data using library programs ■ Carry out statistical analysis on a calculator.

□ Degree or equivalent in mathematics including statistics □ Experience in computer programming and handling biological data desirable □ Age under 30 □ Appointment as Scientific Officer (£1900-£3000) or Higher Scientific Officer (around £2800-£3700) according to age and experience □ Ref: SB/30/DK. □ Application forms (for return by 12 August 1974), from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Tropical Products Institute, Slough

Crop Storage Engineers

- R & D and advisory work on structures and systems for handling and storage of cereal grains and other crops in developing countries ■ Assist in training of storage technologists from overseas ■ Overseas assignments may be required.

□ Degree or equivalent in Agricultural or Civil Engineering □ Knowledge of agricultural crop production, storage systems and simple structural design work desirable □ Experience in tropical or sub-tropical countries an advantage □ Age under 30 □ Appointments as Scientific Officer (£1700-around £2800) or Higher Scientific Officer (over £2550-around £3500), according to age and experience □ Ref: SA/27/JD. □ Application forms (for return by 12 August 1974), from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB.

Tropical Products Institute
London**Pulp and Paper Technologist**

- Assess potential of fast-growing materials for paper pulp in developing countries ■ Chemical analysis, chemical, semi-chemical and mechanical pulping trials, pulp evaluation and consideration of economics involved.

□ HNC or equivalent in relevant subject □ Broad knowledge of paper-making an advantage □ Age normally under 30 □ Appointment as Higher Scientific Officer (around £2800-£3700) or Scientific Officer (£1900-£3000) □ Ref: SA/25/JD. □ Application forms (for return by 9 August 1974) from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London, EC1R 5DB.

group**
CIVIL SERVICE

(360)

THE UNIVERSITY OF ASTON
IN BIRMINGHAM
DEPARTMENT OF PHARMACY
RESEARCH STUDENTSHIP

Applications are invited from candidates with a good degree in Chemistry (G.R.I.C.), Pharmacy or Biochemistry to work on the isolation and identification of biologically active compounds in selected coal-tar fractions.

The studentship, sponsored by the N.C.B., of not less than £700 p.a. (under review) plus demonstrating fees is tenable at the University of Aston. The successful candidate will be registered for the Ph.D. degree.

Applications, together with the names of two referees, should be sent as soon as possible to Dr A. Z. Britten, Department of Pharmacy, University of Aston, Gosta Green, Birmingham B4 7ET.

(286)

CRYOGENICS RESEARCH
UNIVERSITY OF SOUTHAMPTON
POSTDOCTORAL FELLOWSHIPS

Applications are invited for the following posts commencing October 1, 1974.

DEWAR DESIGN : 1 year

To evaluate use of plastics in portable containers for cryogenic liquids.

LNG HEAT TRANSFER : 2 years

To measure 2 phase condensing heat transfer coefficients on large rig at A.E.R.E., Harwell for LNG heat exchangers.

Applicants should have experience in mechanical/chemical engineering or low temperature physics.

Salaries in range £2,100 to £2,400 (plus F.S.S.U.). Applications with names of two referees to the Deputy Secretary, University of Southampton, Southampton SO9 5NH. Please quote reference Na/254/R.

(278)

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL
SCIENCES

Applications are invited from suitably qualified candidates for the post of

POSTDOCTORAL RESEARCH
FELLOW

to work on a project on the transport of hydrogen ions in algal cells.

The post is available for up to 3 years from October 1, 1974 at a starting salary of £2,118 p.a.

Applications, quoting Ref. Est/47/74J and naming 2 referees, should be sent by August 9, 1974 to The Secretary, The University, Dundee from whom further information is available.

(306)

The Hatfield Polytechnic
Biological Sciences
SRC STUDENTSHIP

Applications are invited for a studentship in one of the following areas:-

Teratology of anti-tumour agents
Neuronal uptake of catecholamines
Physiology of vascular smooth muscle
Lipid metabolism in plant tissue cultures
Algal-biocide interactions
Stored product acarology

Leaf microfilm and disease incidence
Applicants should possess a good honours degree and will be expected to register for a higher degree.

Full details of the projects and application forms may be obtained from: Dr K. Wilson, Department of Biological Sciences, P.O. Box 109, Hatfield, Herts. AL10 9AB.

(298)

UNIVERSITY OF ST ANDREWS
S.R.C. Research Studentship

The successful candidate will register for a Ph.D. and investigate the conditions necessary for in vitro breakdown and re-assembly of microtubule bundles isolated from the ciliate *Nassula*. Electrophoresis and dialysis on a micro-scale, and electron microscopy will be involved. Applicants, preferably graduates in biochemistry with an interest in cell biology and fine structure, should send a curriculum vitae with the names, addresses, and phone numbers of two referees to Dr J. B. Tucker, Department of Zoology, The University, St Andrews, Fife KY16 9TS, not later than July 30, 1974.

(280)

FELLOWSHIPS AND STUDENTSHIPS

UNIVERSITY OF WARWICK
POSTDOCTORAL FELLOWSHIP
IN BIO-ORGANIC CHEMISTRY

Applications are invited for Postdoctoral Fellowships to study (under the direction of Dr B. T. Golding) either reactions catalysed by coenzymes of vitamin B₁₂ or hydrocarbon oxidases. The appointments are for one year in the first instance (commencing as soon as possible) with the possibility of renewal. Salary will be in the range £2,118 to £2,412 p.a. plus threshold payment and participation in F.S.S.U. Further details may be obtained from the Academic Registrar, University of Warwick, Coventry CV4 7AL to whom applications should be returned by September 1, 1974. Please quote Ref. No.: 49/Q/74.

(292)

MEDICAL RESEARCH COUNCIL
RESEARCH STUDENTSHIP

Applications are invited from graduates with a first or upper second class honours degree in biochemistry or biology to study phospholipases in epidermal cells. The work is part of a programme of studies on the contribution of lipid components of subcellular and plasma membranes to the structure and function of the epidermis.

The appointment will be for three years and the successful candidate will register for a higher degree. Applications with curriculum vitae and names of two referees should be made to Dr G. M. Gray, M.R.C. Unit on the Experimental Pathology of Skin, The Medical School, Birmingham University, Birmingham 15.

(288)

university of wales
**university
college of
swansea**

Applications are invited for the following posts:—

Research Fellow

in the Department of Metallurgy and Materials Technology. Applicants should have a Ph.D. degree or equivalent experience and the successful candidate will be required to undertake a fundamental investigation into the elimination of heat treatment faults in general carbon systems in close collaboration with a local carbon manufacturing industry.

The appointment, which will be for one year in the first instance, will be on a scale up to £2,247 per annum, together with F.S.S.U. benefits. The closing date is **Friday, August 2, 1974.**

Technical Officer

in the Department of Metallurgy and Materials Technology, to work on a joint research programme with the Welsh National School of Medicine sponsored by the M.R.C., to develop new materials and material systems designed for medical implant. The successful applicant will be responsible for the fabrication of prostheses and should have experience in experimental work in materials technology, and will be required to collaborate closely with orthopaedic surgeons.

The appointment which will be for three years, will be on a scale up to £2,115 per annum.

The closing date is **Monday, August 12, 1974.**

Department of Zoology

Applications are invited for the vacancy of Research Assistant in the Department of Zoology. Applicants should be recent graduates with an interest in animal behaviour and/or endocrinology.

The appointment, which will be for up to three years from October 1, 1974, will be on the scale £1,425-£1,638 per annum.

The closing date is **Friday, August 2, 1974.**

Further particulars and application forms may be obtained from the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to whom they should be returned by the appropriate date. (283)

**Dunstaffnage Marine
Research Laboratory**

Applications are invited for a three year studentship to work on the role of meiofauna, particularly protozoa, in processes originating from the breakdown of cellulose fibre in marine sediments. The studentship carries with it a substantial equipment allowance. The successful applicant would be expected to read for a Ph.D. and would be required to satisfy University regulations for a higher degree. Application forms and further information can be obtained from the Director, Dunstaffnage Marine Research Laboratory, P.O. Box 3, Oban Argyll PA34 4AD. (313)

**UNIVERSITY OF LEEDS
DEPARTMENT OF EARTH
SCIENCES**

Experimental studies at High Pressures and Temperatures

Applications are invited for the post of **RESEARCH FELLOW** to work in the solubility of water and carbon dioxide in silicate melts at high pressures (up to 10 kbars) and temperatures (up to 1400°C). Applicants should have prior post-graduate experience and qualifications in high-pressure techniques or some related field. The post, funded from a NERC grant, is for up to three years; salary on the scale £1,929 to £2,388 (under review).

Applications should be addressed to Professor P. G. Harris, Department of Earth Sciences, The University, Leeds LS2 9JT, from whom further particulars can be obtained. Closing date August 15. (314)

**THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF MICROBIOLOGY**

Applications are invited for a **S.R.C. POST-GRADUATE STUDENTSHIP** leading to the degree of Ph.D. Several research topics available, details of which can be obtained from Professor J. R. Quayle, Department of Microbiology, The University, Sheffield S10 2TN. Please quote ref R 109/G. (268)

**UNIVERSITY OF LEEDS
DEPARTMENT OF PHYSIOLOGY
M.R.C. Research Studentships**

Applications are invited for M.R.C. studentships in the Department of Physiology, University of Leeds. Applicants should have at least an upper Second Class degree in Physiology or associated subjects.

There is a wide range of research in the department which includes renal physiology, central nervous neurophysiology, electrophysiology of visceral receptors, several aspects of cardiovascular physiology, endocrinology and aspects of energy exchange and temperature regulation.

Application forms and further information on specific topics available from Professor G. R. Hervey, Department of Physiology, The University, Leeds LS2 9JT. Closing date for applications July 27. (315)

**THE UNIVERSITY OF ASTON
IN BIRMINGHAM
DEPARTMENT OF PHARMACY
RESEARCH FELLOW**

Applications are invited for the above post which will involve working in the Departments' Pharmacological Laboratories. The Fellow will be a member of a team, led by Professor C. B. Ferry, working on the physiology and pharmacology of normal and disordered neuromuscular transmission. Experience with electrophysiological techniques is essential.

Commencing salary will be within the range £1,929 to £2,223 per annum on a scale rising to £3,378 per annum. With effect from October 1, 1974 commencing salary will be within the range £2,118 to £2,412 per annum on a scale rising to £3,636 per annum.

Requests for application forms (which should be returned not later than August 5), should be sent, preferably on a postcard, quoting Ref. No. 982/6 to the Staff Officer, the University of Aston in Birmingham, Gosta Green, Birmingham, B4 7ET. (285)

**THE POLYTECHNIC OF NORTH LONDON
Faculty of Science and Technology
Research Opportunities**

A number of studentships, assistantships and research awards are available. Their value, and conditions of tenure, vary; further details will be sent on request. In most cases a first or second class honours degree (or equivalent qualification) is required, and the holder will be able to submit the results of the work for a higher degree.

The research projects are in the following fields:

Biology: genetics, biochemistry.

Chemistry: bio-inorganic, chemical analysis, heterocyclic compounds, natural products, reaction mechanisms and kinetics, fast reaction kinetics, nmr and mass spectroscopy, metal complexes, X-ray crystallography, waste utilization.

Physics: spectroscopy, magnetic properties of thin films, cosmic ray physics.

Polymer Science and Technology

Please reply, giving full details of experience and qualifications, with subject and class of degree, names and addresses of two referees, dates when available for interview, and area of research proposed, to the Academic Secretary of the Faculty Board:

**Dr. J. Charalambous, Chemistry Department
The Polytechnic of North London
Holloway Road, London N7 8DB**

(299)

UNIVERSITY COLLEGE DUBLIN

DEPARTMENT OF CHEMISTRY

Applications are invited for a Postdoctoral Fellowship in Organic Chemistry to investigate tautomerism in heterocyclic acyl enamines. The study will involve straightforward synthesis and stopped flow kinetic measurements. The fellowship will be supported by the National Science Council of Ireland. The appointment will initially be for one year, from October 1, 1974, with a possible renewal for one or two further years.

Salary will commence at £2,100 per annum.

Applications, accompanied by a curriculum vitae, and the names of two referees, should be sent to:

Dr R. A. More O'Ferrall
Department of Chemistry
University College
Belfield, Dublin 4.

(331)

POSTDOCTORAL FELLOWSHIP

Applications are invited for a postdoctoral fellowship for an investigation of the use of a cusped-Gaussian basis for the construction of molecular wave functions. Applicants should have a Ph.D. degree and experience in computational quantum chemistry or allied field.

The appointment will be for two years from October 1, 1974. Salary: £2,118 to £2,247 with F.S.S.U. benefits. Application with the names of two referees should be sent to Dr E. Steiner, Department of Chemistry, University of Exeter, Stocker Road, Exeter, EX4 4QD to reach him not later than August 16, 1974. Please quote ref. 1/12/7077.

(324)

RESEARCH STUDENTSHIP IN NEUROPHARMACOLOGY

University College London

A M.R.C. studentship, leading to a higher degree, is available for a graduate with a 2:1 or 1st class degree in pharmacology or physiology and biochemistry or a related science to join a unit studying the release of neurotransmitters in the mammalian central nervous system.

Applicants should send their c.v. and names and addresses of two referees by July 26, to Dr R. A. Webster, Dept. of Pharmacology, University College, Gower Street, London, WC1E 6BT.

(329)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF NEUROLOGY

RESEARCH STUDENTSHIP IN EXPERIMENTAL NEUROPATHOLOGY

Applications are invited for two Research Studentships, tenable from October 1, 1974, to work on histological, ultrastructural and histochemical aspects of experimental myopathies. Facilities are also available for collaborative work involving tissue culture and muscle physiology. Candidates should have a 1st or 2nd class honours degree in a biological science and will be eligible for registration for the degree of Ph.D. The award will be at the usual rate for Ph.D. students. Applications, including a full curriculum vitae and the names of two referees to:

Professor W. G. Bradley,
Muscular Dystrophy Research Laboratories,
Newcastle General Hospital,
Newcastle upon Tyne, NE4 6BE.

(330)

CHELSEA COLLEGE—UNIVERSITY OF LONDON

DEPARTMENT OF PHARMACY

RESEARCH STUDENTSHIP IN MEDICINAL CHEMISTRY

One S.R.C. (C.A.S.E.) studentship is available for a research project involving a study of structure/activity relationships in a series of bridgehead nitrogen compounds and the requirements of the analgesic receptor, to be carried out in co-operation with Allen & Hanburys Ltd. The studentship is subject to normal S.R.C. conditions and applications are invited from candidates with a good honours degree in Chemistry or Pharmacy.

The successful applicant will be expected to register for a higher degree.

Applications to:

Dr J. Walker,
Pharmacy Department,
Chelsea College,
University of London,
Manresa Road, London, SW3 6LX.

(335)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF PURE AND APPLIED CHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from graduates in Physics, Chemistry, Chemical Physics or other relevant disciplines for an S.R.C. Postdoctoral Fellowship.

The successful applicant will work on Energy Transfer Studies using the tunable Spin Flip Raman Laser in collaboration with Drs R. T. Bailey and F. R. Cruickshank, and the laser physics group headed by Professor S. D. Smith at Heriot-Watt University. Most of the experimental work will be carried out at Heriot-Watt.

The post will be for a period of one year in the first instance commencing on September 1, 1974 or as soon as possible thereafter, with possibility of extension for one further year. Salary will be up to £2,058 per annum (under review) with placing according to age and experience and will attract one further increment if the appointment is extended for a second year.

Applications (quoting R25/74) should be sent to Dr. R. T. Bailey, Department of Pure and Applied Chemistry, University of Strathclyde, Thomas Graham Building, 295 Cathedral Street, Glasgow G1 1XL.

(282)

UNIVERSITY OF SUSSEX

Research Studentships in Biochemistry

Applications are invited for:

- (1) An M.R.C. studentship to study either the control of protein synthesis in mammalian cells or some aspect of the growth control mechanisms operative in cultured human lymphocytes.
- (2) An S.R.C. studentship for studies on the mechanism of hormone action. Investigations into protein hormone-membrane receptor interaction and adenylate cyclase involvement in hormonal control processes in the adrenal cell are contemplated.

Applicants are expected to have a first or upper second class honours degree in Biochemistry or a related field, and should send a curriculum vitae and the names of two referees to Dr J. E. Kay (1) or Dr D. Schulster (2), School of Biological Sciences, University of Sussex, Brighton BN1 9QG.

(325)

COLAISTE NA HOLLSCOILE GAILLIMH

UNIVERSITY COLLEGE GALWAY

DEPARTMENT OF EXPERIMENTAL MEDICINE AND PRACTICAL PHARMACOLOGY

RESEARCH STUDENTSHIPS

Applications are invited from graduates in Biochemistry, Pharmacology, Physiology or related disciplines, who have a First or Upper Second class degree, for two research studentships under the direction of Professor B. E. Leonard. Students will be expected to register for a Ph.D.

Research will be concerned with the development of animal models of psychotic depressions and schizophrenia and will involve the use of biochemical, pharmacological and behavioural techniques; it is expected that the study of clinical material will form part of the investigations.

Stipendium will be equivalent to S.R.C./M.R.C. awards, plus small supplementary payments for departmental duties.

Applications, containing details of academic performance and the names of two referees, should be addressed to Professor B. E. Leonard, Professor of Pharmacology, University College, Galway, Ireland. Closing date—August 9, 1974.

(348)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL FELLOWSHIP IN ELECTROCHEMISTRY

Applications are invited from suitably qualified electrochemists, physical chemists, physical organic chemists or physicists for the two projects outlined below. The newly developed techniques of modulated specular reflectance spectroscopy will be used and supplemented by conventional electrochemical methods.

- (i) An industrially sponsored fellowship to study fundamental aspects of the mechanisms of cathodic hydrodimerisation processes with particular emphasis on the effects of the structure of the electrode/solution interface and the influence of surface active ions. The industrial importance of the work will be fostered by regular contact and the successful applicant will be expected to travel to the United States. For a suitably experienced person, the appointment can be made at a senior level with a salary up to £2,580 plus F.S.S.U.
- (ii) An S.R.C. fellowship for the application of modulated specular reflectance spectroscopy to studies in the area—adsorption on catalytic electrodes, the structure of the electrode/solution interface. Starting salary will be £2,118 plus F.S.S.U.

Applications with a curriculum vitae and the names of two referees should be sent to:

Dr A. Bewick, Department of Chemistry,
University of Southampton,
Southampton SO9 5NH.

(345)

UNIVERSITY OF OXFORD

Dyson Perrins Laboratory

Applications are invited from suitably qualified Organic Chemists for a Postdoctoral Research Assistantship to work on the synthesis and characterisation of sequential polypeptides. The appointment is available for the academic year 1974-5 at a salary according to age and experience up to a maximum of £2,247 with F.S.S.U. Previous experience in peptide chemistry would be advantageous but is not essential. Applications, giving a brief curriculum vitae etc., and naming two referees, should be sent as soon as possible to: Dr J. H. Jones, The Dyson Perrins Laboratory, South Parks Road, Oxford, OX1 3QY.

(344)

UNIVERSITY OF READING

Recent Graduate required in Department of Zoology, to work for three years on a S.R.C. C.A.S.E. Award Project on insecticide research leading to a Ph.D. degree. The project, which will be carried out together with I.C.I. Plant Protection, Jealotts Hill, is an investigation into the biochemical effects of a new insecticide upon insect cuticle. Apply to Professor Williams, Department of Zoology, University of Reading, Whiteknights, Reading. (Ref: MN35).

(366)

QUEEN ELIZABETH COLLEGE
(University of London)

DEPARTMENT OF MATHEMATICS

Applications are invited from suitably qualified graduates for a Science Research Council research Studentship. The successful candidate will work for a higher degree on one of the following: group theory, graph theory, mathematical biology, relativity and cosmology, topology.

Apply at once to Prof. W. B. Bonnor (N), Queen Elizabeth College, Campden Hill Road, London W8 7AH. (334)

KINGSTON POLYTECHNIC
SCHOOL OF CHEMICAL AND
PHYSICAL SCIENCES

RESEARCH ASSISTANT

Applications are invited for a postgraduate research assistantship to work on a project concerning synthesis and physico-chemical studies of Pyrimidines and related nitrogen heterocycles.

The assistant will work under the supervision of Dr D. T. Hurst, F.R.I.C., and will be expected to register for a higher degree. Salary range £1,427 to £1,537 (under review).

Further details and application forms (to be returned as soon as possible) from Appointments Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. (368)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF PHARMACOLOGY

Applications are invited for a Research Fellowship tenable in the Department of Pharmacology. The work will be mainly concerned with the pharmacokinetics of quaternary amines in man. Salary within the range £2,118 to £2,580 per annum and may be higher for a candidate with exceptional qualifications.

Applications, giving details of age, academic qualifications and experience, together with the names of two referees should be received as soon as possible by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/N/276136. (364)

UNIVERSITY OF
BIRMINGHAM

Applications are invited for an S.R.C. C.A.S.E. Studentship for research into factors influencing the allergenicity of various protein preparations in baboons and other experimental animals. The work will be carried out in collaboration with Unilever Research Laboratory, Colworth House.

Applicants should have a first or an upper second class honours degree in a biological science preferably with some experience in immunology. The successful candidate will be expected to register for a Ph.D.

Applications should be sent as soon as possible to Dr D. R. Stanworth, Dept of Experimental Pathology, The Medical School, Birmingham 15. (353)

USED COPIES required of all or any:- Chemical Abstracts 3rd, 6th, 7th, 8th collective indexes and Beilstein Handbuch 2nd suppl. vv 6-27, Index vv. 1-27 and general formula index.

Librarian,
Organon Laboratories Ltd.,
Crown House,
London Road,
Morden, Surrey.

(340)

GRANTS & SCHOLARSHIPS

LARGE TELESCOPE USERS

The Science Research Council invites applications to its Large Telescope Users' Panel for observing time as follows:

- (a) on the 98-inch Isaac Newton Telescope at Herstmonceux during the three months 1975 January to March inclusive; and
- (b) on the 20-inch and 40-inch reflectors at Sutherland during the three months 1975 April to June inclusive.

In considering the allocation of time, the Panel will especially support group applications, particularly where they result from collaboration between a university department and a Royal Observatory.

Applications must be made in respect of proposed programmes that cannot be accomplished on telescopes of smaller aperture, and will be considered by the Panel at its autumn meeting. They should be submitted by August 1 on a form obtainable from the Secretary of the Panel, Mr C. A. Murray, Royal Greenwich Observatory, Herstmonceux Castle, Hailsham, Sussex. (289)

LECTURES AND COURSES

KINGSTON
POLYTECHNIC

Specialist one-year part-time courses leading to LRIC.

1. ADVANCED ANALYTICAL CHEMISTRY

This is a course in modern methods of analysis dealing with classical and instrumental methods of analysis in relation to a range of topics including environmental analysis, computing and analytical chemistry and laboratory automation.

2. ANALYSIS OF BIOMATERIALS

This course includes a consideration of the structure, function and analysis of various types of biomaterials. The principles of analytical procedures are covered (e.g. chromatographic, spectroscopic, enzymic, microbiological and radiochemical methods) and the application of these methods to the analysis of biomaterials is considered.

The courses start in September and are primarily offered to holders of HND/HNC in chemistry. They are also suitable as 'refresher' courses and applicants who do not hold the above qualifications will be considered on their merits. All candidates successfully completing the course will be awarded a Certificate of Supplementary Study (formerly known as an Endorsement Certificate) and subject to certain additional requirements, may qualify for admission as Licentiates of the Royal Institute of Chemistry.

Further information from the Secretary, School of Chemical and Physical Sciences, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel: 01-549 1366, ext 312. (341)

Collected Nature

These specially designed Binders make attractive space-saving files for your **Nature**. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of **Nature**. Two volumes of **Nature** can be preserved in a single binder, (three binders will hold the six volumes published annually) and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains.

These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

**NATURE, Macmillan Journals Limited, Brunel Road,
Basingstoke, Hampshire RG21 2XS.**

Please send me:

BIOLOGICAL ABSTRACTS On Microfilm...

BIOLOGICAL ABSTRACTS on microfilm is convenient for both you and your library.

1. You'll find our abstracts an effective way to identify original papers of interest to you no matter how specialized your research.
2. For the librarian, our large multidisciplinary data base offers the key to increased total coverage of biology and biomedicine without costly duplication. Moreover, this one source data base saves valuable shelf space.

Indexes for the first 50 volumes are also available on microfilm. You can quickly discover the convenience of BIOLOGICAL ABSTRACTS on microfilm — write or call BIOSIS today for complete information. BioSciences Information Service, 2100 Arch Street, Philadelphia, Pa. 19103 U.S.A., Telephone: (Area Code 215) LO 8-4016.

biochemicals

New

Reverse Transcriptase

from Avian myeloblastosis virus (AMV)

cat. no. 15644 150 units*

produced with DEAE-cellulose, phosphocellulose and gel-chromatography

tested with poly-A · d [pT]₁₀₋₁₂ and oligo-dT primed AMV-mRNA

identified by the AMV-reverse transcriptase antibody reaction
(inhibition ~ 90%).

***Activity:** One unit is the enzyme activity which incorporates 1 pmole dTMP into an acid precipitable product with poly-A · oligo-dT as template primer in 1 min. at 37° C. The preparation contains bovine serum albumin for its stabilisation.

Shipping: The enzyme is shipped in dry ice to avoid loss of activity.

INSTANT OCEAN®

Culture Systems

Model CS-60

Recreate ecological niches from arctic waters to tropical seas, follow complete life cycles, maintain large numbers of marine organisms for teaching or research, monitor the effects of pollution, conduct corrosion studies. . . . Aquarium Systems' INSTANT OCEAN® Culture Systems and Synthetic Sea Salts make possible the study of the marine environment anywhere in the world.

These Culture Systems are easy to set up, require a minimum of maintenance, and are practically "automatic" in operation. They provide control of the important parameters including temperature control, percentage of oxygen saturation, removal of CO₂ by gas exchange, oxidation of nitrogenous wastes, and continuous pH buffering.

SEND FOR FREE BOOKLET TODAY...

Free with each Instant Ocean Culture System... "MARINE AQUARIUMS IN THE RESEARCH LABORATORY" by John M. King and Stephen Spotte. This 40-page booklet covers the principles and practices necessary to successfully maintain research specimens in closed seawater systems.

Diamond or Abrasive Wheel Cut-off Machine MODEL GSP 210

Cuts Rock, Refractories Ceramics Glass or Metals

A simple to operate machine with application in all fields where hard materials are cut.

The vice unit will grip either regular or irregular specimens, and has a detachable vee jaw for clamping rods, cores or tubes.

Coolant pipes on both sides of the cutting wheel supply ample cooling during cutting. The machine can be supplied with a settling tank and pump unit if required.

Additional equipment—cross slide with 2½" movement.

High speed vibration free taper roller bearing spindle.
Standard Cutting Wheels, 8" diameter x 1/16" or 1 mm wide.
Area of cut 5" x 2½"—Drive flat nylon belt.—
Dimensions—length 30", width 28", height 16". Wt. 1 cwt.

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. *exp (a)* is preferred to *e^a* if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Manipulation of sexual physiology by brain stimulation in insects— <i>M. Moulins, A. Girardie and J. Girardie</i>	339
Properties of a calcium channel in snail neurones— <i>N. B. Standen</i>	340
Resistance of mitotic B lymphocytes to cytotoxic effects of anti-Ig serum— <i>R. S. Kerbel and M. J. Doenhoff</i>	342
Yeast-mycelial conversion induced by N-acetyl-D-glucosamine in <i>Candida albicans</i> — <i>N. Simonetti, V. Strippoli and A. Cassone</i>	344
Early visual adaptation in goldfish retinal ganglion cells— <i>A. J. Afanador and A. J. Adams</i>	346

Advances in Steroid Biochemistry and Pharmacology

Volume 4

edited by M. H. Briggs and G. A. Christie

July 1974, xii+326 pp., £7.00/\$18.00.

0.12.037504.4

contents

Cellular biochemical assessment of steroid activity. Daily rhythms of steroid and associated pituitary hormones in man and their relationship to sleep. Chemistry and biological activity of vitamin D, its metabolites and analogs. Effects of corticosteroids on connective tissue and fibroblasts. Interactions between prostaglandins and steroid hormones. Steroid hormones and breast cancer. Adreno-corticotrophic hormone and the control of adrenal corticosteroidogenesis. Author index. Subject index. Cumulative index of titles.

The Systematics Association Special Volume No. 6

The Changing Flora and Fauna of Britain

edited by D. L. Hawksworth

July 1974, xiv+462 pp., £9.20/\$23.75.

0.12.333450.0

This work reviews all the available information to date on the changes in the major groups of plants and animals in the British Isles. Vascular plants, mosses and liverworts, lichens, seaweeds, macrofungi, pathogenic fungi, mammals, birds, freshwater fish, reptiles and amphibians, terrestrial molluscs, freshwater invertebrates, spiders, butterflies and moths, beetles, grasshoppers and their allies, arthropod ectoparasites of man, ants, bees and wasps, and flies, are all considered, and maps illustrating their changes are to be found throughout the volume.

Software for Numerical Mathematics

Proceedings of the Loughborough University conference of the Institute of Mathematics and Its Applications held in April 1973

edited by D. J. Evans

July 1974, xii+450 pp., £10.80/\$28.00.

0.12.243750.0

Here is a book which is intended to promote the exchange of information and ideas on mathematical software—a new discipline of great importance in computing science. The subject encompasses such topics as the construction and analysis of algorithms and computer programs, the critical and comparative evaluation of programs, the user interaction and methodology involved in the interface of algorithms with application to software packages and programming systems and, finally, a variety of issues concerned with the dissemination, maintenance, creation, portability and structure of computer program libraries.

Symposia Mathematica Volumes 11 and 12

Published by The Italian National Institute of Higher Mathematics

This series contains original works and lectures presented by internationally known scholars: mathematicians working directly with the theories discussed will find them valuable and interesting, while physicists, astrophysicists and engineers will also find them useful for further scientific studies. Volume 11 deals with algebra and geometry, Volume 12 with relativity.

Science and Technology of Surface Coating

A NATO Advanced Study Institute on the Science and Technology of Surface Coating held at Imperial College, University of London, in April, 1972

edited by B. N. Chapman and J. C. Anderson

July 1974, xx+466 pp., £14.80/\$41.50

0.12.168350.8

The aim of this volume is to gather together concisely and under one cover, details of the whole range of surface coating techniques available—some currently in production and others still at the research stage.

Although this work is primarily one of a reference nature, it also highlights areas of current research which have only lately appeared in research literature such as harmonic electric spraying.

Scientists don't move

DESCRIBING the British scientific system as positively arthritic, Sir Hermann Bondi introduced a report last week on "Interchange of Scientists" (available free from the Civil Service Department) which is a cautious first step towards easing the joints. It is small comfort that if anything Italy and Germany are even more fixed in their ways.

The report is necessary reading for anyone who worries that the British scientific scene is not so free-flowing and vigorous as its American counterpart, although most who feel that way (and clearly Sir Hermann's Task Force did) must hope that there is more to come and that the group will stay together even just as a continual stimulus to the body scientific and arthritic.

Mobility in the United States is much admired by those who live a trans-Atlantic existence, and with good cause. Scientists and engineers move regularly in pursuit either of greater job satisfaction or more dollars, and few would hazard a guess that they would be doing the same job in five years time. Movement into and out of the civil service, particularly to spend a time in Washington administering a programme they understand well, is something which many excellent scientists do and which gets them much credit in the community. But then 'the community' in the United States much more naturally includes industry and the civil service as well as the universities. Further there is a much greater freedom, it seems, to pay competitive salaries and in particular not to expect a bright young man to wait until he is forty before he begins to profit financially by being a scientist. Thus the problem with stimulating mobility in Britain is ultimately not so much one of improving administrative arrangements and making the physical move less disagreeable as of changing ways of thinking.

The central proposal of the task force (which the government has already promised to implement) is that within the civil service a small unit should be established to facilitate secondment between the civil service on the one hand and industry and universities on the other. Flow should be in both directions. The third side of the triangle—movement between industry and universities—could not be handled by the same unit, but there is an obvious need for an organisation to stimulate interchanges there too. The ever-cautious scientist, scared of venturing into the unknown, will generally be urged out of his shell by the existence of a return ticket to his first employer after a period of, say, two to four years.

The apparent obstacles to mobility which the task force report make stunning reading. The difficulty of moving house, problems with pensions (the university scheme is a particularly difficult one from which to transfer), inadequate allowances for transfer—all testify to feeble-mindedness among scientists and a lack of social responsiveness from employers. It is scarcely believable

that housing is sufficient of an obstacle that the task force has to recommend that "whenever possible, interchanges should be within the same geographical area to avoid moving house". Clearly a spirit of boldness in pushing back intellectual frontiers does not necessarily extend to much else. Not that employers are blameless—"to a large extent, those taking up permanent posts either in the civil service, or elsewhere, are not paid removal expenses". This medieval attitude must surely go.

One of the problems with stimulating mobility is that the potential mover must perceive other areas as attractive. This most certainly is not true at present, indeed the low regard that the three 'wings' of science often hold for each other must often dampen the enthusiasm of even the most willing mover. Furthermore the restraints on recruitment that the civil service has imposed on it ensured that in 1972, for instance, the Principal Scientific Officer grade, which numbers 2,000, comprised only ten who had been recruited from outside the service during the year. And all the signs are that mobility is on the decline. In 1958 half of all university chemists had outside experience. Now less than a third do, and one department of 33 has nobody with external experience!

There is no simple solution to this deplorable situation. The new unit will at least allow a few more temporary exchanges. But ultimately the whole question of the deployment of scientific manpower and the narrowness of institutional and individual attitudes needs penetrating examination. Maybe somewhere along that route the idea of allowing scientists to keep a year of their education in abeyance until their thirties would merit an airing. And it would be good to see more practising scientists in Whitehall.

100 years ago

THE tenacity of life of popular errors is well exhibited in the following extract from the *Californian Horticulturist* :—
 "The influence of forests in drawing moisture from the heavens may be seen from the experience of San Diego, California. Previous to 1863 there was yearly a rainy season, which made the soil nourishing and productive. In 1863 a destructive fire swept over the greater part of the country, destroying the forest and blackening the hills. Since then there has been no rainy season at San Diego." When will public writers learn that forests influence the climate by drawing water, not from the air, but from the soil?

As a result of the Water Act, 1973, river management, water supply and sewage disposal in Britain have now been integrated under the control of new regional water authorities. This is clearly a desirable move which will make planning and coordination easier within the regions. But of course there are still larger issues which must be settled on a national basis, at government level or by cooperation between regional authorities. To assist with these, a Central Water Planning Unit remains as a rump of the old Water Resources Board, under the auspices of the Department of the Environment (DoE), and a new Water Research Centre has been established by amalgamating the Water Research Association laboratories, the Water Pollution Research Laboratory, most of the Technology Division of the Water Resources Board and part of the Development Division of the Directorate General Water Engineering of the DoE.

As far as the study of long term trends is concerned, the CWPU is concerned directly with forecasting demand, and not with predicting how the supply of water (as rainfall) might vary. But the experience of the past three years, which have been very dry by established standards in Britain, has encouraged an awareness of the question of climatic change, and some steps are being taken to look into this problem.

This new weather pattern is seen by climatologists as part of a global trend which is causing droughts in parts of Africa and has also been responsible for bad harvests in Canada and the USSR. For Britain, the implications are that longer dry spells will be broken by occasional very heavy storms. This has serious repercussions for the farmer, but from the point of view of the CWPU reservoirs can be filled up just as conveniently in one or two great cloudbursts as by weeks of standard British drizzle.

The CWPU itself is situated on the banks of the River Thames at Reading, and members of the Unit (then part of the Water Resources Board) were treated to the sight of the river flooding its banks as recently as January 1974; the same high rainfall which produced that rise in the river helped to stock up the surface reservoirs. But the problems of replenishment of underground aquifers cannot be overcome so easily. Some 25 to 30% of the public water supply is derived from underground sources, and in periods of drought what precipitation there is tends to be absorbed in the surface layers of the ground, or runs off as floodwater, without having much effect on the aquifers; 10% less rainfall over a year can result in as much as a 50% drop in aquifer recharge.

Whither water?

Water services in Britain have recently been reorganised, with the Water Resources Board ceasing to exist on April 1, 1974. John Gribbin discusses future plans for water resources in the light of the last annual report of the Board and the growing awareness of the possible importance of climatic change.

This is where the possibility of longer term changes in rainfall becomes important.

The average rainfall of England and Wales has declined over the past five years; but is this a continuing trend, or is it likely to reverse in the immediate future? It is too early yet for panic measures on the strength of such evidence alone, although it is perhaps worth noting that Professor Hubert Lamb has commented that the first 50 years of this century, which are accepted as the climatic normal, were in

sources Board could, if it so wished, use any part of its research funds in support of climatic research. But now any proposal for extending the present investigation (or, indeed, starting any new project) must first go to the DoE before filtering back down through the CWPU or the Water Research Centre. A spokesman for the DoE confirmed recently that proposals for future research along these lines have been discussed with Professor Lamb, who heads the Climatic Research Unit, and that "the proposals are now under consideration by the Department". Meanwhile, the planners have plenty on their plate in working out how to distribute the rainfall we do get, without worrying too much about what might happen to that rainfall in future.

The way the CWPU would like to see things develop is towards what might loosely be termed a 'national water grid'. This would involve transfers from region to region—such as from the Severn to the Thames—and extending the present system of river regulation. Again, however, this depends on how things develop as the new regional authorities feel their way. There is nothing to stop a region opting for

Table 1 Rainfall over England and Wales, for year ended September 30, 1973

Month	Monthly rainfall (mm)	1916-50 Standard average (mm)	Percentage of average
1972			
October	32	92	35
November	99	95	104
December	104	88	118
1973			
January	44	92	48
February	40	66	61
March	24	57	42
Winter	343	490	70
April	67	60	112
May	84	63	133
June	63	55	115
July	91	79	115
August	63	81	78
September	86	76	113
Summer	454	414	110
Year	797	904	88

fact "perhaps the most abnormal period for the past thousand years" in terms of the British climate. What is important is that the CWPU, at least, takes the possibility of climatic change seriously. A spokesman said that they "would be very interested in seeing more work [of this kind] done, and are open to suggestions for programmes of research". The old Board has provided funds for research into the variability of rainfall in the English lowlands at the Climatic Research Unit of the University of East Anglia, but the present situation with regard to the continued funding of such work is not yet clear.

Under the situation which prevailed until April this year, the Water Re-

independence in water supply, and dotting the local countryside with reservoirs rather than 'importing' water from neighbours.

Indeed, the most nationalistic of the Welsh might press the case that England should be made to pay for 'Welsh' water—although the CWPU has a stock answer to that: build a dam across the border and see what happens if the Welsh do try to keep all their water!

In fact, of course, water from Wales is so important because of a coincidence of geography and climate. The water brought in from the Atlantic is dumped conveniently on the Welsh mountains, providing the possibility of storing it near the source of rivers and using it to regulate their flow. This makes schemes

to develop that potential still further more attractive than alternatives, such as barrages at the Wash or in Morecombe bay; indeed, one plan now being studied would involve expansion of the Craig Goch reservoir to produce 500 million gallons a day—more than twice the capacity of the Wash scheme in its latest form.

The Craig Goch scheme is representative of the change in philosophy of the water planners from the days when direct supply from reservoirs to consumers was fashionable. Now, the aim is to use rivers wherever possible, meeting the demand for abstraction by regulating the flow using reservoirs at the head of the river. This also improves the health of the river, as well as making it possible to take out more water than from a comparable 'wild' river.

Because of this philosophy of river regulation, the planners must now take increasing account of weather forecasting on a day-to-day basis. If water is released from a reservoir during a dry spell to maintain the flow of a river, it could be embarrassing if heavy rainfall a couple of days later were to occur lower down the river just as the surge from the reservoir arrived. This has provided one of the closest direct links between the old Board and the Meteorological Office in recent years, when both have collaborated with Plessey Radar Ltd and the Dee and Clwyd River Authority on a radar weather forecasting project which has formed part of the River Dee Regulation Research Programme.

Apart from the new outlook on surface water management—which depends very much on the cooperation of the new regional authorities—there are also plans to develop groundwater abstraction. In the tenth (and last) Annual Report of the Water Resources Board (HMSO, 79p) it is suggested that resources will be available to maintain the proportion of water derived from aquifer storage until the end of this century, even though total demand is expected to double by then. In the long term, there is the possibility of artificial recharge of aquifers from wells or by

Craig Goch reservoir

“infiltration” through lagoons or basins; pilot projects carried out in the London Basin, in Nottinghamshire, Sussex and other parts of England and Wales have shown the feasibility of refilling some strata with water and abstracting the water when required, and research into and development of such techniques must clearly have very high priority in the plans of the Water Research Centre and the CWPU.

But one superficially attractive proposal for the future seems to have been ruled out for some time to come. Desalination has been widely mooted as a practical system of obtaining pure water in Britain, because of the extensive coastline. But studies suggest that it will be simply too expensive in the fore-

seeable future (the next 25 years), especially when the rising costs of fuel are taken into account. In addition, the environment lobby, which by and large seems to favour the idea of desalination, has not, perhaps, taken full account of the impact on the coastal environment of unsightly desalination plants. Just about the only economically viable use of these plants in Britain at present would be to top up the supply of coastal resorts in the summer, when their population rockets and demand is highest (indeed, desalination is used in just this way in the Channel Islands). But on the other hand, the authorities of areas which depend on the income obtained from visitors attracted by the natural beauties of the coast are the least likely to authorise construction of new industry.

However the investigation of climatic change develops, the question of water supply is bound to occupy an increasingly important place in the thoughts of planners around the world as population increases. Desalination will obviously be important in some areas, if not in Britain. But the problems with desalination as a commercial proposition highlight the truth that although “two thirds of our planet is covered by water” we must think very carefully indeed about where we are going to get a drop to drink in the year 2001 □

Table 2 Water Resources Board expenditure on research

Financial Year	Research £	Section 90* £	Total £
1966-67	31,265	17,948	49,213
1967-68	41,260	41,553	82,813
1968-69	63,866	121,604	185,470
1969-70	120,878	107,998	228,876
1970-71	259,967	167,254	427,221
1971-72	226,679	194,027	420,706
1972-73	237,111	293,686	530,797
1973-74 (estimated)	436,300	347,700	784,000

* “Section 90” is the section of the 1963 Act which empowered the Water Resources Board to provide financial support for work and research carried out by the then river authorities.

international news

AN appeal to the scientific community by a committee of the National Academy of Sciences to refrain from conducting two types of genetic manipulation experiments because of potential hazards to society (see *Nature*, July 19) has drawn a swift and positive response from the National Institutes of Health (NIH). In a letter sent last week to Academy President Philip Handler, NIH Director Robert S. Stone indicated that he will establish a committee to define the possible hazards associated with such research and that NIH is willing to support an international meeting of scientists to discuss the matter.

The academy committee has urged that a moratorium should be placed on experiments which (I) involve the introduction into a bacterium of genes which either confer resistance to antibiotics or cause the formation of bacterial toxins and (II) those which involve the introduction of genes from viruses into bacteria. Furthermore, the committee suggested that experiments which introduce genes from animals into bacteria "should not be undertaken lightly".

The reason for concern is that the bacterium most commonly used for such studies is *Escherichia coli*, which

NIH backing for NAS ban

by Colin Norman, Washington

usually present in the human intestine. But the committee is quick to point out that the concern is "based on judgments of potential rather than demonstrated risk", and that the danger is yet to be precisely defined.

Each member of the committee, which was chaired by Dr Paul Berg of Stanford University, has agreed to eschew experiments of both sorts. And they have called on their colleagues throughout the world to join them in deferring such research until the hazards have been evaluated.

When the committee's statement was made public last week, Berg said that an international meeting is being planned for next February to "discuss whether there are in fact experiments that should or should not be done". The meeting, which will probably be attended by about 100-150 scientists, will not only attempt to define what types of research should be included in the embargo but also for how long it should be maintained.

Asked whether he expects that a

voluntary moratorium will be effective, Dr David Baltimore, a member of the committee, said that at present he knows of no laboratory which is planning to undertake experiments of type I or II, and that peer pressure on scientists now to eschew such studies will probably be sufficient to make the embargo stick. He pointed out, for example, that study groups at NIH—committees of scientists which provide initial peer review of grant applications—will be wary of approving funds for such studies and that the editorial boards of scientific journals will probably think twice about publishing research papers derived from experiments covered by the embargo. "To me", he said, "it is almost unthinkable that scientists would go out and do this type of work now".

The committee acknowledges, however, that its recommendations "will entail postponement or possible abandonment of certain types of scientifically worthwhile experiments". It therefore remains to be seen how long the scientific community will go along with this move toward self regulation, and much will depend on the outcome of the NIH committee's deliberations and next February's international meeting.

What British scientists say . . .

Molecular dirty tricks ban

THE critics of molecular biology are fond of pointing out the scarcity of practical benefits. It is a sad paradox that the very developments which could ultimately have immense value for production of useful, but rare, molecules, should result in an urgent cry of 'halt' from a committee of leading scientists involved, supported by no less than the United States National Academy of Sciences. The amplification of selected genes and their products by synthetic recombination with freely replicating DNA of bacterial plasmids, could, for example, revolutionise the commercial production of substances like insulin, or pituitary hormones, while the bulk synthesis of a transforming gene protein from an oncogenic virus might allow the design of specific antagonists. As more genes are identified on cleavage products of DNA from animal

cells and viruses, so the potential for practical application will increase, to say nothing of the basic knowledge gained.

Yet few will deny the wisdom of the appeal for a moratorium on certain classes of experiment until the implications are more clearly understood. It is not just the risk of unpredicted and explosive self replication of some sinister DNA sequences which causes concern, it is the possibility that by using *Escherichia coli*, the workhorse of molecular biology, the explosion might occur in someone's gut and then be transmitted like antibiotic resistance, throughout the world. No doubt a good many dirty tricks have been attempted and discarded by nature in the course of evolution, but the disquiet arises from the utterly novel associations of genetic material which are now possible. The potential benefits should, therefore,

be delayed, not for ever, but until consequences can be assessed, and preliminary experiments carried out under conditions of maximum security.

Most of the technology involved in all this has been developed in the United States and it is encouraging that the very leaders in the field have taken the initiative and have been supported by the academy. It is now to be hoped that academics and learned societies in other countries will add their weight, and that international organisations such as the European Molecular Biology Organisation will lend support. Granting agencies, and even editors of scientific journals, will also need to consider their policies in the face of wide support for a moratorium. For many it will be a test of self denial and social responsibility in the face of strong intellectual temptation.

Michael Stoker, ICRF

The indiscriminate use of antibiotics has exerted more pressure on the bacterial population than could be wielded by all research workers in the field put together.

from E. S. Anderson, Colindale

THE NAS statement on plasmid engineering evokes a mixed reaction from me. Whatever its justifiability, I wish it had been presented less pompously. We have been more aware since our first experiments in transferable resistance in 1964 that by introducing an R factor into a pathogen we reinforced this organism's pathogenicity with resistance to drugs that might be effective against the respective disease. In particular, when chloramphenicol resistance was introduced into the typhoid bacillus, we were manufacturing a virulent pathogen resistant to the drug of choice for typhoid fever. And we knew that if we presented such a strain with the opportunity of causing infection we would have been guilty of a grave antisocial offence. But R factors had become important in the enterobacteria and they demanded study. We could not do such work effectively if we shirked the step of introducing them into pathogens. So we transferred them to pathogenic enterobacteria, including *Salmonella typhi*, exercising our routine precautions for avoiding infection with the respective organisms, and for their safe storage. We have studied the typhoid bacillus and related organisms for many years, but no infections have resulted from our work, inside or outside the laboratory; so our protective measures must be reasonably efficient. Moreover, it is fair to say that these manipulations have contributed to the understanding of R factors and other plasmids, including the evolution of an easy method for establishing the plasmid nature of elements concerned with enterobacterial drug resistance, virulence or other properties.

The *in vitro* hybridisation of plasmid DNA with DNAs of widely different, even eukaryotic, origin, adds a new dimension to plasmid studies. Once introduced into the bacterial cell, the hybrid plasmids resume the relationships of their bacterial moiety and multiply with the cell. The eukaryotic regions, however, retain their original coding capacity and initiate the synthesis of the corresponding products.

What is the point of such experiments? First, they demonstrate that DNA-DNA hybridisation need not require extensive regions of base-pair homology. They therefore expose processes that may have important evolutionary significance or medical potential. Second, they may help to clarify the *modus operandi* and the nature of the products of the "Xeno-DNA", if one may coin such a term for the introduced foreign DNA. Normally, such

studies are hampered by the relatively slow cell growth and much greater complexity of the respective animals or

tissue cultures. In hybrid bacterial-animal plasmids, synthesis and replication are geared to the much higher kinetics of bacterial growth, so that the respective DNA and its products can be isolated in adequate quantities in a short time. This might accelerate the studies of these materials and could add

Alternative experiments?

SECTIONS of genetic material from any source can now be attached to a bacterial plasmid or bacteriophage and so introduced into the bacterial cell where they replicate quickly and can be recovered in relatively large amounts. By-passing the normal biological barriers between species in this way means that completely novel genetic combinations can be created and disseminated.

But it is at present impossible to predict all the properties and ecological consequences of these new genetic arrangements. Not unnaturally this has led to widespread concern over possible biohazards from such research, which has resulted in the National Academy of Sciences appeal. Concern is enhanced because the ubiquitous human enteric bacterium *Escherichia coli*, has been used as the organism in experiments carried out so far.

Anxieties arise on two main counts. (1) It is generally impossible to transpose selectively only those DNA fragments with known functions. Potentially harmful DNA fragments, such as those containing possible oncogenes, may unwittingly be transferred to a new host where their expression may not be properly controlled. (2) The vehicles used (in the work published so far) to transfer foreign DNA fragments to *E. coli* were plasmids that carry genes determining resistance to antibiotics.

The NAS embargo covers two types of experiment (which have already been accomplished by some of the signatories of the statement), namely the transfer of genes determining drug resistance between bacterial strains or species that do not normally carry such resistance, and the fusion of animal virus genes to transmissible systems.

The NAS request is both reasonable and responsible and deserves to be universally respected. It recognises both the difficulty in evaluating real or potential hazards that may be involved in such work, as well as the obvious criticism that these will remain obscure in the

absence of experimental study; urgent consideration of the latter is explicitly recommended.

Fears that the proposed limitations to experiments will seriously obstruct research in vital areas of biology seem unfounded. The NAS initiative, by focussing attention on the hazards involved, could well promote rather than hinder work on *in vitro* recombination in animal viral systems, an area believed by many to hold the key to gene therapy in its broadest terms. Similarly, the constraints on experiments with plasmids determining drug resistance need not preclude cautious use of the plasmids for cloning certain DNA fragments. Many experiments in this latter area can also be undertaken with bacteriophage λ which is a safer vector for *in vitro* recombination in that it has strict host specificity and carries no drug resistance determinants; it has the great additional attribute of bringing a wealth of genetic and biochemical experience to the service of studies on the cloned fragment of DNA. Use of phage λ does not, of course, eliminate hazards associated with the incorporation of unknown genes.

In view of the anxieties expressed, the wisdom of using a normal human enteric bacterium as host organism in these experiments might be questioned. Certainly there is no reason to believe that one could not select quite different microbial and viral systems that do not inhabit man or mammals, but the hazards, real or potential, would apply equally well to other ecosystems and thus eventually raise the same problem. To do this, however, would be to forsake the wealth of information and experience with *E. coli* and its viruses accumulated from decades of research. This would be prodigal to say the least.

While welcoming the NAS initiative, one is also appreciative of Anthony Tucker's perspective in his comment "Life Stylists" (*The Guardian*, July 19); equally, if we follow the moderate tone set by the NAS we shall be careful not to oversell the social benefits devolving from recent experiments.

Ken Murray, Edinburgh

substantially to the understanding of the respective systems. By hybridisation of oncogenic viral genomes with bacterial viruses or plasmids, cancer workers could perhaps selectively enrich the return of oncogenic material for study.

The signatories of the NAS letter define two types of experiment on which they recommend a moratorium. Type I comprises experiments in which plasmids coding for drug resistance or potential pathogenicity are introduced into pathogens or innocuous bacteria. The fear is of the risk to treatment if a newly resistant pathogen reached its host; or of the emergence of new pathogens that might become ecologically important. *In vitro* construction of plasmids for new drug resistance would also be suspended.

Type II experiments in the NAS letter are those involving hybridisation of plasmid with eukaryotic, or oncogenic or other viral DNA. Such hybridisation might create hazards of an unforeseen nature, since the potential of the hybrid genome cannot be accurately predicted. Hybrid plasmids may thus have oncogenic or other potential for man or other animals. And since the enterobacteria, most widely used for plasmid study, are ordinary inhabitants of the human or animal intestine, they may by accident or design enter the intestine of a suitable host, spread, and act as the vectors of cancer and related diseases, perhaps with augmented virulence or on an epidemic scale.

A sense of proportion must be retained in considering these matters. The widespread and indiscriminate use of

antibacterial drugs in man and animals has exerted immeasurably more pressure on the bacterial population than could be wielded by all the research workers in this field put together. These drugs are used prodigiously in human and animal medicine, and as animal feed additives. The long-predicted results, now realised, were the spread on a gigantic scale of transferable drug resistance plasmids in the ordinary intestinal bacteria such as *Escherichia coli*; and the emergence of epidemic drug-resistant and lethal lines of enterobacterial pathogens: *Shigella dysenteriae* I (Shiga's bacillus) in Central America, the typhoid bacillus in Mexico, India, South Vietnam and Thailand, and *S. typhimurium* and other salmonellae with massive drug resistance and apparently increased virulence in many countries. This has been the direct consequence, not of plasmid work, but of commercial pressures and administrative and professional irresponsibility.

For these reasons I feel little inclination to respond to the call for a moratorium on type I experiments in the NAS letter.

Hybrid plasmids formed by the introduction of normal, and oncogenic and other viral DNA, may present a potential threat, but it is difficult to see how this could be evaluated. Experiments on animals that are the natural hosts of particular viruses spring to mind. But these may not reveal potentialities of the hybrids that might be expressed in different animals. Naturally, tissue culture would be used and the range of experimental animals would include primates, but if negative results are obtained in these, how and

when can we be sure that the chimaeric plasmids are innocuous to man or other animals? The risks cannot be quantified as can energy release from nuclear reactions, because the processes are biological and complex, not physical and simple. And the techniques needed for reliable exposure of oncogenic potential may not yet have been devised.

There is therefore a need for caution in the type II experiments. Bacterial vectors of hybrid plasmids can, however, be adequately controlled by the ordinary sterile techniques of laboratories working with pathogens. This would call for technical re-education of the average microbial geneticist or molecular biologist, whose manipulation of bacteria chills the blood of anyone accustomed to handling pathogens. Cultures should be stored securely: methods for doing this already exist. Such precautions, which should be routine, minimise the risk of accidental spread of dangerous pathogens, and no technical distinction should be made between known pathogens and presumed non-pathogens.

Strict isolation techniques must be practised if animal experiments with bacteria carrying plasmids in the type II category are carried out.

The methods needed to maximise safety in such investigations are known, and plasmid researchers must learn them if work on these hybrid plasmids is to proceed. The only alternative is the abandonment of type II experiments, or at least a chosen proportion of them, which may mean the closure of potentially valuable avenues of research. There is a manifest need for expert international debate in this field.

THERE is a particularly irritating television commercial in the United States which contains the classic line that "all aspirin is not alike". Although that phrase was coined on Madison Avenue to make money rather than to make a scientific point, it is typical of the claims that are flying around in a bitter dispute between pharmaceutical manufacturers and the federal government over the quality and price of American drugs.

The dispute is simple enough. The government, backed by consumer groups, argues that a particular drug should produce the same effects no matter who manufactures it, and so government agencies should not throw money away by buying an expensive brand-name drug when the same product is available at a lower price.

But many drug manufacturers take a different view. They maintain that products containing the same ingredients but manufactured in different ways may produce different therapeutic effects. Therefore, they argue, if the

Differences between the same drugs

by Colin Norman, Washington

government insists on buying the lowest priced drugs it may also be getting the lowest quality products.

Last week, the Office of Technology Assessment (OTA), Congress's new scientific think tank, stepped into the debate. In its first report, prepared by a panel of ten eminent biomedical scientists, OTA provided at least partial backing for the arguments of the drug industry by stating that many drug products are not interchangeable, chiefly because shoddy manufacture and poor enforcement of quality standards by the federal government do not guarantee therapeutic equivalence.

The OTA panel, chaired by Dr Robert W. Berliner, Dean of the School of Medicine at Yale University and former Deputy Director of the National Institutes of Health, cited a number of

"well-documented and significant differences" between drug products that are supposed to be chemically equivalent. The differences, in fact, were not confined to drugs made by different manufacturers, but also cropped up among different batches of drugs made by the same company.

Perhaps the most clear-cut and alarming incidence of such disparities came to light during a study carried out at a New York City Hospital in 1971, which was singled out in the OTA report. That study turned up evidence that four different brands of a highly potent heart drug, digoxin, were so strikingly different in their effects that the peak concentration of the drug in the bloodstream differed by a factor of seven. Yet the margin of safety of digoxin is so narrow that lethal effects can occur if the dose given is only twice that needed to produce a therapeutic effect.

The OTA panel reckons that there is probably "roughly a score of drugs" for which there is evidence of dif-

ferences in so-called bioavailability among brands which are supposedly chemically equivalent. And it suggests that such differences have resulted in therapeutic failures or inadvertent poisonings when patients have been given doses containing too little or too much of the prescribed drug.

The importance of the OTA's findings is that they have a direct bearing on proposed new policies governing payment for drugs by the federal government. On December 19 last year, the Secretary of Health, Education and Welfare, Caspar Weinberger, sent a shiver of apprehension through the pharmaceutical industry by announcing that the federal government would limit the price paid for drugs under the state-run Medicaid and Medicare programmes to "the lowest cost at which the drug is generally available". About \$1,300 million is paid each year for prescription drugs under those programmes, and Weinberger estimated that the new policy would save between 5 and 8% of the costs.

But last week the Pharmaceutical Manufacturers' Association (PMA), the trade association which represents nearly all the big United States drug makers, claimed that the OTA report "completely undercuts the ill-advised proposal" for drug purchasing, because it challenges the basic principle that chemically equivalent drugs are interchangeable.

Berliner pointed out last week, however, that for most drug products biological equivalence is not critical because there is a wide margin of safety between the dose needed for therapeutic effects and the toxic dose. He reckoned that only "about 10 to 15%" of the drugs on the market may pose a problem because of therapeutic differences between brands.

Science studies in Amsterdam

by a Correspondent

At a time when the values of scientific activity are increasingly being questioned, so social studies of science are being included as optional or compulsory courses in universities round the world. British experience in this field—particularly that at the Universities of Edinburgh, Manchester and Sussex—has achieved considerable note during the past few years. So therefore it comes as no great surprise, even in these times of fluctuating interest in European collaboration, that the programme of teaching and research in science studies at Edinburgh will be the model for an unusual new unit at the Free University in Amsterdam. Moreover, British and Dutch collabora-

Confiscated manuscripts

by Vera Rich

THE scheduled date of the Moscow "seminar that never was" has passed, and the would-be organisers and participants have been, at least temporarily, released from custody—yet the history of this valiant venture in academic freedom seems far from complete. As might be expected, the attention of the authorities is still focused on Professor Aleksandr Voronel, whose Moscow apartment was to have been the venue of the seminar. On Friday July 19, 1974, his apartment was subjected to an 8-hour search by the

police who confiscated some 2,000 papers, mostly scientific manuscripts, including those submitted by intending participants in the international seminar. On the same day, the fourteen-year-old son of Dr Benor Gurfel, another of the seminar sponsors, was stopped in the street on his way to deliver certain manuscripts to Professor Voronel. These were also confiscated.

Professor Voronel and his wife are under constant and obvious surveillance, and are at present staying away from the apartment. This confiscation of manuscripts is seen by informed observers as an ominous sign—the intensive campaigns against major dissidents such as Solzhenitsyn began in precisely this way.

ration is further strengthened by the appointment from August of a British historian of science and former palaeontologist, Dr Martin J. S. Rudwick, from the Department of History and Philosophy of Science, Cambridge, as the unit's first director and also as the first professor of History and Social Studies of Science in the Netherlands.

The Free University has long had a liberal attitude to the education of its science students. A course in general philosophy has been compulsory since the university's foundation in 1880 and history of science was added to the curriculum of all students in the late 1940s on the appointment of the noted historian of science, Dr R. Hooykaas, as professor. When Professor Hooykaas retired—about the time of the student unrest in the Netherlands at the end of the 1960s—it was decided that it would be expedient to widen still further the scope of the curriculum by introducing courses in science and society. For the past two years staff from the History and Social Studies of Science Division at the Science Policy Research Unit, convened by Dr R. M. MacLeod, have helped Dr E. Boeker, Professor of Physics in the Natural Sciences Laboratory, to prepare the ground for the new unit which will be the cornerstone of the Centrum Algemene Vorming (Centre for General Education) in the Faculty of Mathematics and Natural Sciences.

All first and second year students in the five departments of the faculty must now attend 52 lectures a year on philosophy, and the history of 'science and society'. Since 1972/73, teaching has been divided between the staff of the science and philosophy departments and visiting scientists from industry as well as guest lecturers from Sussex. The Sussex staff have also assisted with the seminars for the science and society 'minor' option

which graduate students can take during their fourth and fifth years.

When Dr Rudwick assumes his appointment in August, the unit will then start acting as general co-ordinator of all the courses in general studies, including those at present taught by the different departments—the so called encyclopaedia. The first PhD student in science studies at the Free University (a physicist who is currently taking the MSc course at Sussex) will register next year and it is hoped that in time the unit will be able to carry out a regular programme of research. Dr Rudwick's present interest is the social and conceptual history of science; to complement this, it is expected that staff who specialise in the sociology of contemporary science will eventually join him in the Centrum.

Although science studies and science policy units are found in other universities on the continent—for example, at Heidelberg and Lund—they are usually separate from the central core of the science faculty. At the other five universities in the Netherlands, some science and society courses are available, but these are not as widely based as that offered at the Free University in Amsterdam. Chemistry students seem to be the most privileged in this respect; at the State University of Groningen, for example, the chemistry department offers a major in 'free chemistry' with courses in chemistry, physics, economics and sociology. There has been some success in introducing discussions on ethical problems into biology courses, but in physics and mathematics departments there has been more resistance, though in the department of physics at the Technical University, Eindhoven, students can do a minor in physics and society.

No takers

A WEALTHY businessman's plans to give grants to young scientists for basic biological research ended in disenchantment on both sides at a meeting in London recently, when it transpired that he would not consider any applicant who held any sort of religious belief.

Mr Ray Turner had hoped to set up a foundation to award grants to young biologists under 28 years old for "independent fundamental research into outstanding questions relating to the chemical organisation of life". The grants were to be at a rate 20% above the United Kingdom universities non-clinical academic scale with tenure for 5 years initially and the opportunity for repeated extension; in effect allowing the possibility of a lifetime's financial support.

Thirty-six applicants who, under the terms of the application, had been nominated by senior researchers, assembled at the Strand Palace Hotel at Mr Turner's expense for an informal meeting to present their research proposals for selection.

As most of them expected some sort of scientific panel, they were surprised to find only Mr Turner, his wife and Professor Bellamy of the Zoology Department at University College Cardiff, the 'scientific coordinator' who had signed the original circulars inviting applications which were sent to university heads of departments in early June.

Each applicant was asked for a brief resumé of his work and aims, and his ideas of "the single basic facet of the really great scientist". Mr Turner then said that he wished to ask a question which might surprise some people but that the motive would be explained later.

He then asked if anybody had religious beliefs. Four applicants put up their hands and their names were noted. The rest were then asked whether any of them held any belief in a "supernatural plan". More put up their hands and their names were also noted. The remainder resolved, after lively discussion, into what Turner classed as agnostics and atheists.

As it had become clear by now that selection was not going to be made on conventional scientific grounds, most of the participants thought that this might be some sort of 'management selection technique' but during lunch Mr Turner had a private discussion with one of the participants, Peter Leadley, who had put up his hand in the first group. Mr Turner told him that although he was considered among the most promising of those present, he could not be considered for a grant on account of his religious beliefs.

Now it's legal

Reactor in the Alps

It was a symbolic occasion at Grenoble last week as the ministers from Great Britain, France and West Germany signed an agreement bringing Britain into equal partnership with the other two countries in supporting the high flux neutron beam facility at the Institut von Laue-Langevin. Symbolic, because the partnership has existed *de facto* since January 1973. And yet, such is European collaboration on other things that since then the three countries have been trying hard to find a convenient date for ministers to participate in a ceremony giving tangible evidence that in some fields an international spirit still prevails.

The institute is hardly unfamiliar with symbolism; it exists in large part because France and Germany needed some collaborative scheme in the mid-1960's to patch up relations—indeed folklore goes so far as to say that Professor H. Maier-Leibnitz was asked to propose a project, suggested a high flux reactor and so it was. Not that it is in any way a white elephant. There was an urgent need for such a facility to further research in all fields from nuclear physics to biology, and it is

widely agreed that the institute is fulfilling its purpose admirably.

The 57-MW reactor was built by French and German firms and first went critical in August 1971. It delivers a maximum flux of 1.5×10^{15} neutrons $\text{cm}^{-2} \text{s}^{-1}$ and, in addition to supplying thermal neutrons to up to 50 separate experiments, has a cold source—25 litres of liquid deuterium as a low temperature (25 K) moderator—and a hot source—10 litres of graphite as a high temperature (2,000 K) moderator.

The main use of the neutrons so far has been in the study of condensed matter. Neutron diffraction can determine crystal structures, including the location of light atoms which are inaccessible to X-ray diffraction. Long wavelength neutrons are used to study defects and biological structures. The magnetic moment of the neutron is a valuable tool in understanding magnetic materials, and inelastic scattering is being used in studies of the dynamics of atoms and molecules.

As would be expected the scientific staff is international in character, although the British, who have been pioneers in neutron techniques, face problems in uprooting themselves for a period of several years in that return to a Britain with a depressed job market in high-flying science is bound to cause worries. On the other hand British technicians there speak with enthusiasm of their conditions and salary and some are prepared to stay indefinitely.

The running costs of the reactor and institute are £6 million this year but Professor Mössbauer, the director, is seriously concerned about inflation. Commitments in the newly signed document are inadequate for inflationary times and it has not been possible to hammer out tripartite agreement on including inflation automatically into each country's contribution. "As soon as the ink is dry", he said "I have to go back to the sponsors to negotiate more money for next year".

While the scientists were still debating whether even this might be some sort of psychological selection test, Mr Turner announced that he could not consider any of the applicants who had expressed any belief in a religious or supernatural power.

Mr Turner first said that he did not wish to give his reasons but during the three and a half hours discussion that ensued he eventually explained that he felt that if a scientist believed in any sort of supernatural power he would experience conflict in researching problems which enquired into the fundamental nature of life. He therefore thought that the very best scientists, the ones he wished to encourage, could not be religious.

At this point, Professor Bellamy who had taken little part in the proceedings so far, stated his opposition to the method of selection as did several of the 36 scientists, some of whom then left. The rest, according to a participant who stayed, tried to make Mr Turner realise that his sort of criteria could not be used as a basis for selecting scientific work and that it would be unacceptable to the scientific community at large. Mr Turner was asked whether he would consider handing over the money to scientific trustees to administer, but he refused.

Eventually it became obvious that deadlock had been reached and Mr Turner announced that he was withdrawing his offer.

news and views

Nutrition and immunity

As is demonstrated by the communication of Aschkenasy on page 325 of this issue of *Nature*, there is currently a broad focus of interest in the relations between nutrition and immunology. At first glance the association of these two disciplines may seem strange; their union grew from clinical and epidemiological experience in malnutrition and infectious diseases, experience that eventually led to the understanding that either of these conditions tended to augment the other. Many observations, such as that of an increased morbidity and mortality from measles among sub-optimally nourished children, suggested that nutritional deprivation tends to render persons more susceptible to certain disease, and suggested that some aspects of host resistance are functionally impaired. Meanwhile, laboratory workers were amassing evidence in support of the concept that nutritional manipulations could indeed affect the immune response. Much of the clinical and laboratory work concerning the nutrition-infection-immunity cycle was published in 1968 in a classic World Health Organisation monograph (*Monograph Ser. W.H.O.*, No. 57). As it became generally acceptable that the immune response accounts for much of host resistance, it also became more reasonable to ask if malnutrition affects the immune response. Answers to this type of question required the collaboration of nutritionalists and immunologists, and forged a new direction for both sciences.

Studies of nutritional-immunological relationships in man are difficult, for many reasons. In the first instance, pragmatists may assert, with some justification, that the answer to malnutrition is to provide more food. This is of course true, but until more food is provided the problem will exist, and famine and pestilence will continue. Another approach to the problem might be gained by asking what particular components of host resistance are affected by malnutrition, and by the subsequent use of modern immunology, nutrition or public health either to repair the lesion specifically or to circumvent the need for its function. Some persons have maintained that the problem is too complex to study because of the great number of uncontrollable variables. Logistics have been another impediment to the study of nutritional-immunological interactions in man. Malnutrition often exists in areas where medical and research facilities are limited, where weather and terrain are difficult and where many other social and medical problems require priority. In spite of these difficulties, several national and international centres and institutions have begun to construct a matrix of collaboration and communication with the purpose of defining and dissecting some of the effects of malnutrition on the immune response.

For the most part, these studies have sprung from individual efforts, but many of the investigators have elected to coordinate aspects of their studies through the World Health Organisation (*Bull. Wld Hlth Org.*, 46, 537; 1972). The WHO has responded in its usual efficient and effective way by formulating an international collaborative study (*Amer. J. clin. Nutr.*, 27, 638; 1974), the fabric of which has served to strengthen collaboration between national and international bodies, and to extend communications be-

tween field and laboratory workers. More information about this can be obtained by writing directly to the World Health Organisation in Geneva.

Although a great deal of work remains to be done, data from field and laboratory studies thus far do seem to be piecing together a preliminary but coherent picture of the immune response in malnutrition. For example, amounts of serum immunoglobulin (Ig) do not seem to be affected consistently by protein-calorie malnutrition (PCM), but elevated levels, especially of IgA, are not unusual (*J. Pediat.*, 81, 1194; 1972). Increased values for Ig in PCM have been attributed to intercurrent infections (*Archs. Dis. Childh.*, 45, 282; 1970). This seemingly increased synthesis of Ig needs to be reckoned with data that convincingly show serum albumin (*Lancet*, i, 63; 1973) and most components of the blood complement system to be depressed in PCM (*ibid.*, i, 1016; 1973). Amounts of antibody in malnourished persons are also inconstantly affected, but in these circumstances the effect seems to be antigen-dependent; for instance, vaccination against polio or measles produces measurable antibody (*Archos lat-am. Nut.*, 23, 345; 1973); but some viral and several bacterial antigens do not produce a high incidence of seroconversion (*Trop. geogr. Med.*, 18, 125; 1966). These observations would seem to be relevant to current vaccination programmes. They also suggest a clear need for more applied and basic research into problems such as the effectiveness of dietary supplementation before vaccination, the route of immunisation, the type of adjuvants, and the relative T- or B-cell dependance of antigens for human use.

Studies of cell-mediated immunity (CMI) in human malnutrition have suggested that the thymus-derived components of the immunological system are damaged. Indeed, histopathological studies have reported a virtual absence of thymus tissue (*Envir. Child Hlth.*, 217; September 1972). These morphological alterations seem to be mirrored in tests of T-cell function; for instance, results of skin testing for delayed hypersensitivity reactions to many antigens, particularly to tuberculin following BGG vaccination (*Lancet*, ii, 719; 1965), have been reported to be significantly depressed (*ibid.*, i, 506; 1973). Insofar as positive tuberculin reactions are thought to be associated with protection following BCG, the absence of such reactions is likely to be relevant to the incidence of tuberculosis among sub-optimally nourished persons. Other measures of CMI have also been reported to be depressed in malnutrition. The response of human peripheral blood lymphocytes to phytohaemagglutinin *in vitro* is generally regarded as a measure of T-cell function, and this reaction is reportedly suppressed in PCM (*Lancet*, ii, 939; 1971). Numbers of T cells can also be measured *in vitro* by allowing them to form rosettes with other cells, and results using this test have again suggested that malnourished persons have diminished numbers of T cells. The message of these several lines of evidence seems to point to a type of T-cell immunodeficiency in malnutrition. If this is true, it does not, of course, alter the dictum that the answer to the cycle of malnutrition and infection is to provide more food, but it does suggest that perhaps the cycle can be prophylactically or therapeutically approached from another bias.

Several biochemical and cellular events important in the nutrition-immunity-infection cycle have also been studied. Biochemical studies of phagocytic cells from malnourished

persons have reported a depressed glycolytic pathway (*Amer. J. clin. Nutr.*, **24**, 272; 1971), and these defects are reversed when patients are given a diet rich in calories and proteins (*Biochem. J.* **127**, 255; 1972). Functional studies of similar cells have reported a delay in the killing of phagocytosed bacteria, and this defect is also reversed by adequate diet (*Clin. Exp. Immunol.*, **17**, 121; 1974). Another defect in the killing of phagocytosed bacteria is corrected simply by the addition of iron (*Archs. Dis. Childh.*, **48**, 863; 1973). If these various defects represent different mechanisms which are corrected by different types of dietary supplementation, it would seem to be wise to know more about the mechanisms involved. The bacterial-killing defect, which is presumably lysosomal, may be related to the immunodeficiency discussed earlier; for instance, one mechanism for activating macrophages to kill phagocytosed bacteria is by way of products from antigen-activated T cells. This type of basic information is being integrated into modern nutrition and public health programmes, the practical effects of which are yet to be determined.

A great deal of work remains to be done. Almost nothing is known about the effects of intrauterine malnutrition on the development of the immunological system, the long-term effects of early malnutrition on the immune response, or the effectiveness of vaccination programmes in marginally nourished populations (*Lancet*, **ii**, 675; 1972). Answers to these questions would seem to be relevant to public health programmes in both developing and developed countries. Many of these questions can be addressed to animal models as has been done by Aschkenasy (*Immunology*, **24**, 617; 1973) and many others. This brief comment has not covered experimental models because of their obvious importance. Neither immunologists nor nutritionists pretend to have an answer to the malnutrition-infection cycle, but their combined approach has broadened understanding of an area of human biology that concerns us all.

W. PAGE FAULK

Evolution of nucleotide-binding proteins

ONE of the most fascinating questions about the formation of life and its immediate development is how the enzymes needed to sustain the basic life processes were derived. It seems reasonable that the relatively large number of enzymes required by even a primitive bacterium were derived from a much smaller number of basic, relatively non-specific enzymes—probably by gene duplication and subsequent divergence leading to a diversification of function and a narrowing of specificity. On this basis it would be expected that the large number of present-day enzymes could be grouped into a much smaller number of families, each of which was derived from a common ancestor. But if the common ancestor is very remote, there may be insufficient indication from the amino acid sequence to establish relatedness. On the other hand, since it is known from the evolutionary studies of the globins, the serine proteases and the cytochromes that tertiary structures change very slowly, X-ray diffraction studies of protein structure seem to be the most promising method for identifying family relationships. During the past year or so X-ray structure determination of a number of intracellular metabolic enzymes have produced some exciting results that seem to provide the basis for characterising an extensive family of nucleotide-binding enzymes.

The structural relationship was first seen clearly when the structures of liver alcohol dehydrogenase (LADH) (Brändén, *et al.*, *Proc. natn. Acad. Sci. U.S.A.*, **70**, 2439;

1973) and glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (Buehner *et al.*, *ibid.*, 3052) were compared with the homologous lactate and malate dehydrogenase (LDH and MDH) molecules. The polypeptide chains of all four dehydrogenases, composed of between 327 and 374 amino acid residues, are folded into two distinct units or domains. One of these domains is responsible for binding the common NAD cofactor and the other domain carries the binding site for the specific substrate of each enzyme and its catalytic site. In all four molecules the NAD-binding unit has a common fold that is characterised by a β -sheet core composed of six parallel strands (A-F), with a strand order CBADEF, and by a similar disposition of the mainly α -helical intrastrand loops above or below the sheet. The NAD cofactor is bound to the domain at an equivalent site in all four molecules. Earlier, Rao and Rossman (*J. molec. Biol.*, **76**, 241; 1973) had found that this domain seemed to be composed of two similar three-stranded units each associated with the binding of a mononucleotide, and they proposed that this unit was utilised to bind flavin mononucleotide in flavodoxin and to form the aromatic specificity site in subtilisin. In sharp distinction to the similarity of the NAD-binding domain, the catalytic domains, except in the case of LDH and MDH, are structurally quite distinct.

This pattern of relationship was subsequently observed in phosphoglycerate kinase (PGK) (Blake and Evans, *J. molec. Biol.*, **84**, 585; 1974; and Bryant, Watson and Wendell, *Nature*, **247**, 14; 1974), where the suggestion that the ATP binding domain of PGK has the characteristic fold and binding site of the NAD binding domain has been confirmed by the latest results. As with the dehydrogenases the catalytic domain has a distinct structure. The nucleotide-binding domain corresponds to the N-terminal part of the chain in LDH, MDH and GAPDH and the C-terminal part of the chain in LADH and PGK.

This pattern of structural relationships points strongly towards the evolution of the NAD-binding protein by gene duplication of the mononucleotide binding unit and its subsequent incorporation in the dehydrogenases, and probably in a modified form in the kinases, by a genetic fusion process involving protein fragments carrying the specific binding and catalytic properties of each particular enzyme. This hypothesis can only be established by amino acid sequence comparisons. Those comparisons of dehydrogenase sequences that have been made failed, however, to reveal this striking relationship, probably because the remoteness of the common ancestors makes it very difficult to align the sequences.

Rossman, Moras and Olsen in last week's issue of *Nature* (**250**, 194; 1974) reported that these problems could be overcome by using the structural and sequence data together to trace the evolutionary history of the nucleotide-binding unit. By superposing the hydrogen bond arrangement in the β -sheet core, they have been able to determine homologous amino acids in the sequences of the various dehydrogenases, flavodoxin and subtilisin. After aligning the sequences in this way, the calculation of the minimum base change per codon was used as a measure of the elapsed time since the occurrence of a common ancestor. The evolutionary tree produced in this way is consistent with the divergent evolution of the nucleotide-binding unit of the dehydrogenases and flavodoxin from a common ancestral binding protein. This common ancestor seems to be exceedingly remote and Rossman and his colleagues suggest that it is older than 3.2×10^9 yr, indicating that it may have been present during precellular evolution. Though evolutionary relationships need many data to establish them with any certainty, this analysis seems to indicate a line of protein development that is as old as life itself, which may link together two of the largest groups of enzymes, the dehydrogenases and kinases. At the same time it shows that

gene fusion may be an important process in molecular evolution, particularly as it gives the resultant molecule a binucleic structure that is an almost universal feature of enzyme molecules.

The structures of two other enzymes that may also be members of this family have been reported recently in *Nature*. In this week's edition, Campbell, Watson and Hodgson (*Nature*, **250**, 301; 1974) describe the structure of phosphoglycerate mutase (PGM) determined by a 3.5 Å resolution electron density map. The molecule is a tetramer of four identical subunits, whose polypeptide chains are about 220 residues long. The core of each subunit is formed by a 6-stranded β sheet, in which four parallel strands are followed by an antiparallel pair, flanked by five of the six α helices in the subunit. Though the order of the β strands is not the same as that in the nucleotide-binding unit, the linear order and spatial arrangement of the five flanking helices is remarkably similar to that of LDH, although PGM has no known nucleotide-binding capacity. The authors show how the strands in the β sheet may have been rearranged if PGM has evolved from an ancestral protein with LDH folding, but at the same time point out that the general helix-sheet structure observed in these molecules may represent a particularly stable fold and imply, therefore, that it could be the property of more than one enzyme family.

The other enzyme, adenylate kinase (AK) was the subject of three papers in *Nature* for July 12. In the first, Schulz, Elzinga, Marx and Schirmer (*Nature*, **250**, 120; 1974) reported the structure of AK obtained from a 3 Å resolution Fourier map. The enzyme's single polypeptide chain has 194 amino acid residues and it is folded into two domains, the larger of which has a five-stranded parallel β -sheet core with a BCADE strand order. Although X-ray analysis of substrate binding has not yet been carried out, the active site histidine is found near two hydrophobic pockets in a position equivalent to that of the adenine and nicotinamide binding sites in the NAD-binding unit, that may represent the AMP and ATP binding sites. In the second paper Schulz and Schirmer (*Nature*, **250**, 142; 1974) report the use of a method for comparing AK with other potentially related molecules that is based on the topologies of their

polypeptide chain folds. They define a "figure of topological relatedness" as the triple product of the number of ways of ordering the strands in a β sheet, the number of ways the connecting loops can be disposed on either side of the sheet and the number of possible locations for binding sites. The figure of relatedness is highest when AK is compared with subtilisin and lower, but still significant when AK is compared with flavodoxin or the dehydrogenase nucleotide-binding unit.

Schulz and Schirmer point out that topological comparisons cannot be used to distinguish convergent and divergent evolutionary relationships. But a more fundamental problem in using topologies or defining structural pathways to relate molecules with somewhat different chain folds is that such methods are not supported by any firm knowledge of the chain folding process. The best that can be done in this direction is demonstrated in the third article on AK, by Schulz and the "Who's Who" of the structure prediction world (*Nature*, **250**, 140; 1974). Using the joint probability of up to ten different prediction methods, they show that α helices, β -sheet strands and reverse turns can be predicted from the amino acid sequence with a fairly high degree of success, for this particular molecule at least. Although this is very promising, there is still a long way to go before, for example, the strand order in a β sheet can be predicted. Until this can be done structural comparisons must be treated with caution. Unlike its amino acid sequence, the tertiary structure of a protein reflects changes in the genetic material in an essentially unknown way and is likely to undergo discontinuous changes, such as the rearrangement of the order of strands in a β sheet, that have no intermediates. In these circumstances it would be unwise to use structural comparisons as more than indicators of possible evolutionary relationships. Though such relationships can only be established by sequence comparisons they are best carried out in the light of the structural information. It is by no means impossible that within this large group of apparently closely and more distantly related enzymes there are both homologous and analogous relationships, and it is vitally important to distinguish them if the path of molecular evolution is to be accurately traced.

C. C. F. BLAKE

State of play in the neural hypothesis of muscular dystrophy

THE most striking clinical and pathological change in the muscular dystrophies in man is the severe and progressive degeneration of the skeletal muscles in the absence of clinically or pathologically significant peripheral nerve abnormality. The motor nerve, however, is known to have a very marked effect on the function and metabolism of the skeletal muscle. The finding by McComas and Mrozek¹ that 27% of skeletal muscle fibres in mice with muscular dystrophy were denervated suggested that the motor nerve may have an even more important part to play in regeneration. Further studies showed a marked decrease in the number of motor units in the extensor digitorum brevis muscle in Duchenne and other human muscular dystrophies²⁻⁴, and in murine muscular dystrophy⁵. As a result of these studies, McComas and colleagues propounded the hypothesis that muscular dystrophy is caused by the "sick" motor neurone, the abnormal influence of which on the skeletal muscle fibre caused it to break down.

This hypothesis received support from the experiment of Salafsky⁶ in which muscle transplanted from dystrophic mice into normal hosts regenerated with the physiological characteristics of normal muscle. Further support came from

Gallup and Dubowitz⁷ who found that dystrophic mouse spinal cord would not support the regeneration of muscle in tissue culture, whereas normal spinal cord supported full regeneration both of dystrophic and normal muscle.

Much of this original evidence in support of the neural hypothesis has now been called into question. Harris and Marshall⁸ have failed to confirm the finding of denervated fibres in murine muscular dystrophy and have suggested that the original findings by McComas and Mrozek could have resulted from hypoxia of the preparations leading to artefactual presynaptic failure. Panayiotopoulos and colleagues^{9,10} and Ballantyne and Hansen^{11,12} have both criticised the technique used for motor unit recording by McComas and colleagues, and by more refined techniques have found that the number of motor units in the extensor digitorum brevis muscle of patients with various muscular dystrophies is normal. Several groups of workers have obtained results entirely contradictory to those reported by Gallup and Dubowitz^{13,14}. Preliminary results in my laboratory suggest that the contraction believed by Salafsky⁶ to arise from the transplant may in fact have been transmitted from the host's underlying normal muscles to which the transplant

is intimately fibrosed (unpublished work of A. Montgomery, W. G. Bradley and M. Jenkinson). Abolition of the contraction of these host muscles virtually abolishes the tension produced by the transplant.

Despite the contradiction of many of the basic observations leading to the neural hypothesis, experiments which bear on the nerve in muscular dystrophy are still being performed. In reviewing these it is important to remember that there are several different diseases both in man and in animals which have been classed under the title of the muscular dystrophies, and that the aetiology of each may be different. Desmedt and Borenstein¹⁵ found that motor nerves in patients with Duchenne muscular dystrophy are quite capable of sprouting to reinnervate denervated muscle fibres, and thus show no sign of being 'sick'. The total number and structure of the anterior horn cells in human Duchenne¹⁶ and murine muscular dystrophy¹⁷ are normal. Focal peripheral nerve abnormalities are found in murine muscular dystrophy but not in Duchenne dystrophy or in dystrophic hamsters¹⁸. The peripheral nerve abnormality in mice both of the 'severe' (dydy)¹⁹ and 'benign' (dy²³dy²³) (my and M. Jenkinson's unpublished work) forms of muscular dystrophy consists of a decrease in the number of Schwann cells and apparent arrest of myelination at the foetal stage of axons in the anterior and posterior roots, and the proximal parts of certain peripheral nerves. Axons run through these areas to become myelinated distally. My group has found that this abnormality of Schwann cell investment and myelination is present in the lumbo-sacral and cervical anterior and posterior roots, disappears with normal myelination in the region of the dorsal root ganglia, but recurs several millimetres distally in patches in the upper part of the lumbo-sacral plexus. We have also found it in the facial and trigeminal nerves.

These dystrophic mice also show an abnormality of axoplasmic flow in the peripheral nerves, with a decrease in the amount of slow flowing protein¹⁹ and of choline acetyl transferase²⁰, and an increase in the amounts of faster flowing proteins, phospholipids and cholesterol^{19,21,22}, with a probable decrease in the amounts of the fastest ('superfast') flowing proteins²¹. An abnormality of the peripheral nerve proteins probably derived from myelin has been reported in dystrophic mice²³.

Peterson's technique²⁴ of chimaera formation from normal and dystrophic mouse morulae is of considerable interest. He used isozymes to follow dystrophic and normal nuclei in the mouse which developed from these morulae. Some skeletal muscles had up to 94% of dystrophic nuclei, and many individual muscle fibres had only dystrophic nuclei. Despite this there was little or no pathological degeneration of these skeletal muscles. Conversely in some of

these mixed chimaeras, muscle containing no dystrophic nuclei sometimes showed pathological changes. The data suggest that in these mice the muscle degeneration is caused by some extramuscular abnormality. Peterson suggested that this might lie in the motor neurones, but it could equally be some abnormality conveyed in the blood stream.

This study is very important, and it must be extended to other enzyme markers, and to other animal models of muscular dystrophy. It is important to remember that the study does not necessarily apply to man and that the short history of the neural hypothesis is scattered with apparently conclusive studies which fail to be confirmed by other workers. Thompson and colleagues have pointed out²⁵ that the neural hypothesis will not explain what is known about female carriers of the gene for Duchenne muscular dystrophy. According to the Lyon hypothesis, half of the neurones of these carriers will contain a single active X chromosome carrying the dystrophic gene, and half the normal gene. The creatine kinase level in the blood of a carrier might therefore be expected to be half of the level in a male with Duchenne muscular dystrophy of the same age if the neurone caused the skeletal muscle breakdown. This prediction is not substantiated, the values of creatine kinase being much lower.

The state of play may be summarised as follows. Much of the original basis of the neural theory has been contradicted, but neural abnormalities both of structure and function have been found in murine muscular dystrophy. The muscle degeneration in the latter may be of extramuscular origin though the chimaera experiment needs further study. On the whole I consider that there is little incontrovertible direct evidence for the neural hypothesis and that it remains likely that a primary muscle degeneration occurs in many, if not all, of the muscular dystrophies.

There are reasons to turn attention to membrane abnormalities in the muscular dystrophies. There is some suggestion that the sarcolemma leaks creatine kinase at the earliest stages of Duchenne muscular dystrophy, some months or years before muscle fibre necrosis begins²⁶. Red cell membrane abnormalities have been seen with the scanning electron microscope both in murine²⁷ and human Duchenne²⁸ muscular dystrophy, though preliminary studies in my laboratory have failed to confirm acanthocytosis in murine muscular dystrophy, nor demonstrate abnormalities of plasma lipoproteins. It would, however, clearly be interesting to study the other muscular dystrophies with the techniques which have enabled Roses, Appel and colleagues to identify biochemical abnormalities in the membranes of patients with dystrophia myotonica^{29,30}.

'Hot' hydrogen initiates amino acid production

from D. O. Hall

It is just 21 years since Miller reported his now classic experiments in a paper entitled "A Production of Amino Acids under Possible Primitive Earth Conditions". This non-biological synthesis of amino acids by sparking for a week a gaseous mixture of methane, ammonia, hydrogen and water vapour initiated a new phase of research on the origin of life. Since then an impressive list of many different amino acids, sugars, aromatic hydrocarbons and nucleotides and nucleosides have been synthesised using various energy sources such as sparking, heat, ultraviolet (UV) light, α , β and γ rays, and shock waves. These experiments are well described in Miller and Orgel's recent book *The Origins of Life on the Earth* (Prentice-Hall, New Jersey; 1974).

The sulphur-containing amino acids which are so essential components of proteins have been conspicuous by their absence among the products of all these types of experiments. In 1971, however, Sagan and Khare (*Science*, 173; 417) solved this problem by including H_2S in a UV-irradiated gas mixture which included methane, ammonia, ethane and water; cysteine was produced as one of the six amino acids detected. The H_2S provided the source of sulphur and importantly also provided the means by which UV light at wavelengths below 266 nm could be absorbed as an energy source to catalyse the prebiotic synthesis of organic compounds. These authors calculated that about 200 kg of amino acids could have been produced by UV light absorbed by H_2S per square centimetre on the primitive Earth in 10^9 years. This large amount of amino acids must have allowed a high concentration to accumulate even allowing for considerable destruction by other processes.

Hong, Hong and Becker (*Science*, 184, 984; 1974) have now confirmed and extended this earlier work by showing that H_2S or CH_3SH (methyl mercaptan) can act as UV photon absorbers and can initiate by releasing 'hot' hydrogen atoms the production of up to nine amino acids, including the important cysteine. Whereas Sagan and Khare reported that a two-carbon substrate such as ethane is required to produce amino acids, Hong *et al.*'s experiments worked well with just the one-carbon methane. A simple mixture of H_2S , NH_3 , CH_4 and H_2O will produce nine amino acids but interestingly

cysteine may require a two-carbon substrate in order to be synthesised. These authors state that the amino acids produced were in the free form and were not breakdown products of polymers which would have formed as polypeptides—as was suggested by Sagan and Khare. These differences in experimental procedure and products may be important in future 'prebiotic experiments' where the aim is to synthesise polypeptides.

The 'hot' hydrogen atoms produced by the action of ultraviolet light on H_2S or CH_3SH have kinetic energies of about 17 to 32 kcal mol⁻¹, which is sufficient to provide the activation energy for the synthesis of organic compounds in interstellar space or on the primitive Earth. That these types of syntheses may occur in interstellar space has become a real possibility with the recent discoveries using radio astronomy, of compounds such as ammonia, hydrogen, hydrogen cyanide, acetaldehyde, methyl alcohol and hydrogen sulphide in interstellar clouds. In 1971 Buhl reviewed this rapidly developing field (*Nature*, 234, 332; 1971) and concluded with this fine paragraph: "The important parallels appear to be between the formation of interstellar molecules and the synthesis of amino acids in prebiological chemistry experiments. It is here that the key to the evolution of interstellar molecular clouds lies".

Limited progress at GR7

from P. C. W. Davies

ALTHOUGH the location of the Seventh International Conference on Gravitation and General Relativity at Tel Aviv University from June 24–28, was somewhat controversial—few Eastern European countries were represented and some eminent Western relativists were also absent—nevertheless, there was a generous sprinkling of familiar names among the participants and the usual atmosphere of conviviality seemed unimpaired.

On the theoretical side, only modest progress seems to have been made since the sixth conference in Copenhagen. Both S. Deser (Brandeis University) and J. Goldberg (Syracuse University) made discouraging remarks about quantum gravity, reinforcing the prevailing opinion that traditional covariant quantisation techniques are going round in circles, while only hinting at the possible direction of more radical approaches. At a less sophisticated level, the recent claim by Hawking that quantum field theory in a classical gravitational field predicts the disinte-

gration of microscopic black holes seemed to have been readily accepted in spite of the rather unusual nature of the result. (Hawking himself was not present.) The effect was discussed at some length by W. Press (California Institute of Technology) in a summary of astrophysical processes occurring near black holes. Helpful review talks on cosmology and exact solutions were delivered by R. Matzner (University of Texas) and W. Kinnersley (University of Montana) respectively, and a sparkling account of exotic mathematical developments connected with the BMS group was given with much humour by E. Newman (University of Pittsburgh).

The experimental results were rather more dramatic. M. Rees (University of Cambridge) gave a spirited and carefully balanced review of the theoretical and observational aspects of the detection of black holes, concentrating particularly on the situation regarding the X-ray source Cygnus X-1. Having presented some evidence to suggest that this source has a mass of at least $6M_\odot$, he commented that explanations of this object involving models of differentially rotating white dwarfs or three-body systems seemed "contrived and *ad hoc*", and that in his opinion Cygnus X-1 was instead a "strong candidate" for a black hole. Characteristically, his optimism was tempered by the remark that this was "not a firm conclusion", but that the balance of evidence did seem to favour the black hole explanation. If this was so, then there was a new opportunity to test general relativity by examining the behaviour of the accretion disk which would surround such an object and produce the X rays, possibly by relating this behaviour to curious fluctuations in intensity which have been observed from this source.

By far the most controversial issue of the conference was left to the last day, with a panel discussion on gravitational wave detection. During the past few months the interpretation of J. Weber's epic experimental data in terms of gravitational pulses from the galactic centre has been increasingly open to doubt. The subject reached a new peak of controversy with the presentation of results from other similar experiments being carried out in Munich/Frascati, Glasgow and the Bell Telephone Laboratories/University of Rochester. First, Weber (University of Maryland) reasserted his existing position in confident and ebullient style, claiming a further high event rate for the period May 21–June 15, 1974 using improved equipment. He did admit, however, that the use of a new algorithm favoured by other groups led to a greatly diminished event rate, but asserted that his original algorithm had a very much better detection efficiency.

P. Kafka (Max Planck Institute,

Munich) described the Munich/Frascati data since August 1973, claiming a substantial improvement on sensitivity over Weber, but with no significant events detected. R. Drever described data from his wide bandwidth detector in Glasgow during the period September 1972–April 1973 with the same result—no effect. He described the situation as “saddening” and went as far as to express the opinion that Weber was probably mistaken. Finally, J. Tyson (Bell Telephone), claiming a sensitivity for the Bell Laboratories/Rochester experiment very much greater than other experiments, also reported no events.

In view of the importance of the issue at stake, the atmosphere remained remarkably restrained. Weber countered the negative results of his colleagues by rejecting their claims of higher sensitivity. When challenged on the all-important issues of the sidereal anisotropy (which seems to indicate a correlation of his events with the centre of the galaxy), Weber seemed to be saying that he had not yet checked recent data for this effect because of other pressures. The overall impression was that the issues involved hinge on complicated technical details, but that Weber's position among the experimentalists is now growing increasingly isolated as more and more experiments fail to confirm his data.

Stranded whales in Britain

from our
Marine Vertebrate Correspondent

THE gathering of data on stranded cetaceans on the coast of the British Isles has now been in progress for well over half a century. Because of the special historical claim that the Crown had over ‘royal fishes’ on much of the English, Welsh and Scottish coasts, the collection of reports of strandings was already in progress and their publication on a regular basis was a logical step which was initiated by the late Sir Sidney Harmer in 1913.

The latest *Report on Cetacea stranded on the British Coasts from 1948 to 1966* compiled by Fraser (No. 14, 1–65, 9 maps; British Museum (Natural History) 1974, £3.00) contains a full listing of the reported stranded cetaceans (with notes on a few sightings) on the British and Irish coasts for the eighteen year period to 1966. It is unfortunate that even the most recent records in the report are now eight years old, and that the opportunity has not been taken to bring the list as nearly up to date as possible. Nevertheless, there is much of interest in the accumulated records despite their age, and there is good reason

in bringing them all together in the hope that common patterns will emerge from the data.

Among the records of especial interest is the full documentation of two strandings of narwhal (*Monodon monoceros*), both in 1949 (February and July), a species known to have been found only three (or possibly four) times before. A pair of narwhals was also reported as sighted off the Orkneys in June 1949. The white whale (*Delphinapterus leucas*), only stranded once before since 1913, was sighted on three occasions (1948, 1950 and 1965) off the British Isles, and, as Fraser points out, was also reported off the French coast in December 1948, and in Dutch waters in June 1965 and 1966. The coincidence in some of these dates of sighting and later stranding suggests that the same specimens may have been involved in some cases, but this is not possible to confirm. What may also be significant (although Fraser does not comment on this) is that these two species are both Arctic cetaceans which occurred in unprecedented numbers in 1948–1949 in European waters following a winter of unusual severity in 1947–1948.

Other records of particular interest in Fraser's report are the first recorded occurrence of the pigmy sperm whale (*Kogia breviceps*), off Co. Clare, Ireland, in April 1966, and two unrecorded strandings of the euphrosyne dolphin (*Stenella coeruleoalba*). This species had hitherto only been reported twice (1937 and 1939) in British waters, but the two additional records predate these, one based on an old photograph of 1923, and the other on a skull in the British Museum collection, previously identified as a common dolphin, which was stranded in 1934.

The total number of identified stranding since record keeping began in 1913 now amounts to 1,550. Of these 631 were of the common porpoise (*Phocoena phocoena*), 185 of the bottle-nosed dolphin (*Tursiops truncatus*) and 135 of the common dolphin (*Delphinus delphis*). By analysis of the occurrences of the common porpoise, Fraser has shown that strandings occur most frequently during the period July to October, with small peaks in January to March, and on the central and southern North Sea coast. Fraser cites earlier literature which suggests that there is an annual migration out of the Baltic between November and February, and conjectures that this may be correlated with the summer-time peak of strandings on the East Coast of Britain. The pattern of records which Fraser presents is certainly in keeping with the suggestion that porpoises enter the North Sea mainly in the northern sector and then follow the main current systems southwards

in an anti-clockwise direction. On the other hand, the incidence of strandings seems to be high in each of the major bights round the English and Welsh coasts, and the southern North Sea and the eastern English Channel can be seen as particularly large bights. The explanation for the distribution of porpoise strandings may thus be due to the configuration of the coast line and possibly the presence of shoal water, rather than to purely biological phenomena such as annual migrations of the animals.

Lead accretion in alluvial deposits

from Peter D. Moore
Plant Ecology Correspondent

THE release of undesirable but easily recognised substances into the environment, during such processes as mining and industrial smelting or by the explosion of nuclear devices, does have certain compensations. It can provide datum levels in recently deposited sediments which allow the calculation of accretion rates. For example, Bradbury and Waddington (in *Quaternary Plant Ecology*, edited by Birks and West, Blackwell, Oxford, 289; 1973) have used the abundance of haematite granules in the recent sediments of Shagawa Lake, Minnesota, to determine ediment ages. Haematite grains first appear in the sediments when iron ore mining began in the area in 1889 and reached a peak in 1902 when production was maximal; subsequently they declined gradually until 1951 when there was a sharp decrease corresponding to a decline in mining.

The isotope caesium-137 has been used as a datum in both peats and limnic sediments (for example, Pennington, Cambray and Fisher, *Nature*, **242**, 324; 1973). Fallout reached a maximum in 1963 following the widespread proliferation of nuclear testing above ground. Lee and Tallis (*Nature*, **245** 216; 1973) have used aerial lead fallout to provide datings of stratified peat deposits in the Southern Pennines.

Davies and Lewin (*Envir. Pollut.*, **6** 49; 1974) have also studied lead, but this time in alluvial deposits of the River Rheidol. The build-up of alluvium in the meander loops of the river has been mapped or photographed on eight occasions during the past 130 years; this has allowed the successive zones of alluvial soil to be dated fairly accurately. The upper catchment of the Rheidol has been mined for lead since Roman times, but peak activity occurred during the nineteenth century. Davies and Lewin have analysed the zones of alluvial soils in an attempt to determine the effects of these activities

upon the floodplain materials of the river.

Deposits laid down in the period 1845–1886 had the highest concentrations of lead (1,500 p.p.m. dry soil). Following this, in the zone 1886–1904, values dropped to 1,011 p.p.m.; the fall could reflect the 1876 Act of Parliament requiring the cleansing of mine effluents. Mining ceased at about 1900 and the subsequent zones have lower concentrations of lead: 1904–1951, 785 p.p.m.; 1951–1971, 503 p.p.m.; 1972, 368 p.p.m.

These data show that, despite the reworking of older deposits during the formation of meanders, the lead contents of alluvial soils do reflect the contemporary conditions of lead pollution in the river. This technique could be used for the historical studies of alluvial pedogenesis in similar situations but where precise mapping is unavailable. The accumulation of heavy metals in alluvium is also a salutary reminder that the precise drainage conditions which make these soils the recipients of leached and eroded plant nutrients, producing high fertility, also result in the concentration of the toxic materials eroded from the catchment. The advisability of using such alluvial soils for arable agriculture or grazing will depend on conditions of river pollution during the period in which accumulation of the substrate took place.

Evaporation and gas exchange in nature

from P. S. Liss

THE evaporation of water from natural water bodies is largely controlled by aerodynamic processes in the air above the water surface. By contrast, exchange of sparingly soluble gases, such as oxygen, carbon dioxide, nitrogen and the inert gases, across air–water interfaces in the environment is almost entirely dependent on the degree of turbulence in the liquid phase. This fundamental difference leads to very different approaches in the study of evaporation and gas exchange in nature. For instance in order to describe evaporation, sophisticated mathematical treatments of atmospheric turbulence are necessary, whereas it seems that simple laminar models can go a long way towards elucidating air–water exchange rates for dissolved gases.

In order for water molecules to evaporate from a water surface they must have sufficient energy to escape from the liquid. Furthermore, the aerodynamic regime in the air above the interface must be such that the water molecule is prevented from con-

densing back onto the surface. At the 22nd Bat-Sheva seminar, which this year took for its subject "Mechanism of Evaporation and Gas Exchange in Nature" and was held from June 16–30 at the Weizmann Institute of Science, Rehovot, W. H. Brutsaert (Cornell University) presented a detailed mathematical treatment of evaporation and showed how semi-empirical theories of atmospheric turbulence can be used to help solve the differential equations involved. These lectures were complemented by those of C. B. Tanner (University of Wisconsin) who reviewed the practical methods so far used to measure evaporation rates over land surfaces. He illustrated the importance of such studies by pointing out that evaporation represents on average 70% of the total outflow from catchments in the United States. In arid regions the figure may rise as high as 95%. The best estimates of evaporation seem to be those based on measurements of the energetics of the process, especially when these methods are locally calibrated. G. Stanhill (Volcani Center, Bet-Dagan) led a discussion on the various methods of preventing evaporation from water bodies and plants. For open waters, monolayers have been tried, but it is hard to maintain a continuous film at the surface when there is any appreciable wind. Pumping cold water from the bottom of the lake to decrease the temperature of the surface and so reduce evaporation is a novel technique which deserves attention. There has been some success in laboratory experiments in which plant leaves are sprayed with a chemical in order to increase their stomatal resistance and so reduce evapo-transpiration, but such techniques do not seem to work well when applied to crops in the field.

A laminar layer model has been used by W. S. Broecker (Lamont Geological Observatory) to characterise exchange of sparingly soluble gases across the air–sea interface. From measurements of Rn-222 and its parent Ra-226 near the water surface, it is possible to calculate the thickness of the laminar layer at the sea surface. From such measurements, made as part of the GEOSECS programme in the Atlantic and the Pacific, there are now reasonable average values for gas exchange rates in the major oceans. These values can be used to calculate the fluxes of many atmospheric trace constituents (both natural and anthropogenic) across the sea surface. S. Emerson (Swiss Federal Institute for Water Protection) showed how similar techniques have been applied in lakes to obtain rates of CO₂ transfer across the interface. His results indicate that, despite reports to the contrary, dissolved carbon is unlikely to be a limit-

ing factor in algal growth in lakes, because CO₂ can transfer from the atmosphere to the water at a rate fast enough to supply the carbon required for phytoplankton growth.

The molecular structure of liquid water was considered by R. A. Horne (Arthur D. Little Inc.). Of especial importance in the context of the seminar was his analysis of how the properties of the very surface layers of water molecules (vicinal water) differ from those of the bulk liquid. Vicinal water seems to differ from the bulk fluid over a wide range of physical (freezing point, viscosity, thermal expansion) and chemical (solubilities of ionic and non-polar solutes) properties, but its thickness is still a subject of much debate.

Thermal disruption in the asthenosphere

from Peter J. Smith
Geomagnetism Correspondent

THE possibility that nonlinear viscous heating could produce thermal runaways in the Earth's interior was first recognised by Gruntfest (*Trans. Soc. Rheol.*, **7**, 195; 1963) who used the heat equations to show that, for one-dimensional plane viscous flow under constant stress in a slab, the temperature and strain rate may become arbitrarily large in finite time under adiabatic or near-adiabatic conditions. Many of the ideas initiated by Gruntfest were then later applied by Shaw (see, for example, *J. Petrol.*, **10**, 510; 1969) and Shaw *et al.* (*Bull. geol. Soc. Am.*, **82**, 869; 1971) to specific geological situations such as the rheology of basalt, the relation between Earth tides and magmatism in the Sierra Nevada, and Hawaiian volcanism. More recently, Fujii and Uyeda have been quoted as having used the ideas of both Gruntfest and Shaw to explain the size of intrusive dykes and the eruptive history of volcanoes.

But talk of magmatism, volcanism and viscous flow leads naturally to deeper thoughts about the asthenosphere in mind that O. L. Anderson and Perkins (*J. geophys. Res.*, **79**, 2136; 1974) have been looking again, but in a rather different way, at the possibility and implications of thermal runaways in the Earth. They begin by drawing attention to the fact that the heat flow equation applicable to one-dimensional viscous flow at constant stress is the same one-dimensional equation as that used to describe thermal explosions in solids, and then go on to explore the consequences of this connection between two apparently quite different situations. The fact is that the common equation implies fea-

tures common to both processes; and this, in turn, suggests that the known characteristics of one process may be used to predict the properties of the other; for example, solid explosives possess instabilities which, when triggered, produce the explosion. The fact that viscous flow is governed by the same basic heat flow equation then implies that regions of viscous flow in the Earth (for example, the asthenosphere) should also possess inherent instabilities which, if triggered, should produce thermal runaways.

Insofar as thermal runaways in the Earth were proposed by Grunfest more than a decade ago, this prediction by analogy may not seem particularly useful. Fortunately, however, there is more to be gained, for, as Anderson and Perkins point out, thermal explosions have been studied in some detail, and the knowledge obtained thereby may be used to extend the analogy with viscous flow. Pursuing this line of attack and making reasonable assumptions about the properties of the heat flow equation, Anderson and Perkins conclude that the potential for thermal runaways in the asthenosphere does indeed exist and that the time taken for the temperature to rise to the very high values necessary would probably be a few tens of million years after the initiating event.

Once such a thermal event has been triggered, the hotter material will rise towards the lithosphere in what Anderson and Perkins choose to call a surge. Some of the stronger surges would actually reach the bottom of the lithosphere but would probably not penetrate it. Instead, the surging material would spread out horizontally and then sink as it cooled, although completely circular paths would not be produced thereby because any given surge would die out in about the same time as it took to grow. On the other hand, the time scale involved here is tens of million of years, so that regions of high temperature (hot spots) would be expected to persist near the lithosphere–asthenosphere boundary for periods significant even in geological terms.

The geological implications of such a situation are clearly important. For example, although the hot asthenospheric material itself may not penetrate the lithosphere, its presence immediately beneath would facilitate partial melting in the upper mantle and lower crust, and thus crustal igneous activity. The significant point to note here is that zones of partial melting produced in this way would be distributed irregularly and would thus not necessarily bear any regular temporal or spatial relationship to steady-state subduction processes. Acceptance

of surges would therefore mean that it would be no longer necessary to force complex arrangements of igneous activity into patterns dictated by plate tectonic models. The case that Anderson and Perkins have in mind here is the wide extent and complex patterns of Cainozoic igneous activity in the south-western United States. The problems involved in attempting to explain this activity in plate tectonic terms have already been emphasised by several workers; Noble *et al.* (*Bull. geol. Soc. Amer.*, **84**, 1393; 1973), for example, noted that the late Tertiary volcanic field of south central Nevada contains materials generated from different sources or different levels or both.

Finally, if thermal runaways produce surges in the asthenosphere, what triggers them? Thermal explosions in solids are triggered by thermal impulses and, by analogy, asthenospheric 'explosions' could be initiated by friction at the lithosphere–asthenosphere boundary, mantle plumes or changes in activation energy (for example, by dilution with a suitable volatile). Anderson and Perkins, however, also draw attention to other possible triggers which are less directly thermal and more concerned with changing asthenospheric flow patterns. Examples are the break-up of continents and the replacement of subduction zones by transform faults. It is clear, for instance, that the encroachment of the Pacific ridge on Atlantic plate must have profoundly affected flow patterns in the region and thus severely disrupted the asthenospheric thermal gradients.

Models of the Earth

from P. G. Richards

THE classical subjects of theoretical geophysics dominated a symposium held from June 25 to July 5 at Cambridge: no neat and easily solved novelties here, but the staples of mantle convection, dynamo motions in the core, scattering theory, weather prediction and earthquake source mechanisms.

At a session honouring Sir Edward Bullard, who is retiring from the Cambridge chair of Geodesy and Geophysics, F. Gilbert and A. Dzeiwonski (University of California, San Diego and Harvard) described notable new levels of sophistication in their study of the Earth's free oscillations. Several hundred new modes have been identified, and the inversion of 1066 data yields an improved Earth model in which the source mechanisms of two deep focus earthquakes can be retrieved accurately. Their results back

up a controversial claim, made earlier, that the source region experiences compression, beginning about 80 s before the origin time as determined from body wave observations.

Since 1972, when the International Union of Geodesy and Geophysics sponsored its first symposium on mathematical geophysics, there has clearly been progress in the understanding of the Earth's core. M. Chinnery (Lincoln Laboratory, MIT) gave a new formulation for finding static deformations of an Earth model with a compressible fluid core, showing that current debate and major disagreements in the literature on this subject can be resolved by working with bulk properties in the fluid (density, pressure) rather than with particle displacements. D. Crossley (Memorial University, Newfoundland) presented results for the gravitational undertones in a subadiabatic core of a rotating Earth, finding that eigenperiods are confined to the range 0–12 h. The written versions of these two papers are awaited with interest, for the basic problem has challenged Love, Jeffreys, Pekeris, and many another of the sharpest theoreticians in geophysics.

In weather prediction and seismic wave propagation, it is now possible to recognise statistical elements which limit the deterministic results naively hoped for a few years ago. However well an initial state of the atmosphere is known, C. Leith (National Center for Atmospheric Research, Boulder) reported, there is no basis for predicting atmospheric pressures beyond about two weeks. Likewise, the seismologist should not expect to interpret every detail on a seismogram, although K. Aki (MIT) has used a standard back-scattering theory to determine some interesting differences in the heterogeneity of California, Japan and Norway. Subsequent corridor discussion showed that scattering theories are being widely investigated, as, for different length scales of heterogeneity, completely different scattering modes may be appropriate. Even the standard formulations (based on acoustic waves) may give different asymptotic results for P–S scattering in the elastic case.

The effect of specified inhomogeneity on sufficiently long period waves should, of course, be deterministic, and quite realistic problems are now often attacked with the finite element method. A major computational advance here was reported by W. D. Smith (University of California, Berkeley), who has found a subtle way to eliminate unwanted reflections from the grid boundaries. He uses two sets of boundary conditions for which the sum of solutions sees the boundary as transparent, even for elastic (P–SV) waves.

Fossil marginal basin in the southern Andes

Ian W. D. Dalziel*, Maarten J. de Wit & Keith F. Palmer†

Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964

In the southern part of the South American continent a marginal basin opened behind an active andesitic island arc in the earliest Cretaceous. The basin closed again in the middle Cretaceous, during the period of fast seafloor spreading, causing the penetrative deformation of the southern Andean Cordillera.

THE Andes are widely regarded as the 'type' continental margin orogenic belt¹⁻⁴. The regular Cordillera-bounded, western continental margin of South America is frequently contrasted with the island arc festooned eastern margin of Asia^{5,6}. Our recent field work demonstrates that a marginal basin with a mafic floor, like those behind the island arcs of the western Pacific, opened up in the southern Andes during the Cretaceous as previously suggested by Katz⁷. This has important consequences not only for the history of the Pacific Ocean basin but also for concepts of mountain building at continental margins.

A narrow discontinuous belt of mafic igneous rocks extends along the spine of the Andean Cordillera from Cape Horn at 56°S at least as far north as 51°S, a distance of 350 km (Fig. 1). These rocks, commonly termed the *rocas verdes* (green rocks) by Chilean geologists, were considered to be mainly lavas and have been variously referred to as 'eugeosynclinal' or 'ophiolite' assemblages⁷⁻¹¹.

The belt of mafic rocks is flanked on the Pacific side by the Patagonian batholith, a vast continuous granodioritic body extending from Cape Horn to 50°S and beyond, averaging more than 60 km in width and reaching almost to the continental margin. The continental rocks on the Atlantic side consist of Palaeozoic (? and older) metamorphics unconformably overlain by an extensive silicic volcanic layer 0-2 km thick of middle-late Jurassic age, with a cover of Cretaceous and Cainozoic sediments. The silicic volcanic layer extends in the subsurface as far as the eastern continental margin.

The Patagonian batholith is interpreted as the root of an andesitic volcanic chain initiated in the Late Jurassic and comparable with the Central Andes of today. The *rocas verdes* are thought to represent the mafic floor of a marginal basin that formed in the latest Jurassic-earliest Cretaceous, separating the active andesitic volcanic chain from stable continental South America.

Volcanic chain development

A thick sequence of sediments was deposited in the southern Andes from Kimmeridgian to Aptian time. Along the Atlantic side of the High Cordillera uniform black mudstones of shelf facies were deposited, thickening markedly from 400 m in the east to more than 2 km towards the west. Within the Cordillera a marked facies and a further change in thickness occurs. Abundant, thick greywacke beds and thin radiolarian cherts appear interbedded with the black mudstones. Towards the Pacific where the sequence exceeds 3 km, the greywackes thicken and become more abundant¹². They are rich in immature

andesitic volcanic detritus, which suggests the presence of an active volcanic source during sedimentation. Variations in thickness and facies indicate that the source lay on the Pacific side of the sedimentary basin. The presence of andesitic lavas and volcanic breccias in the southern part of the basin, interbedded with the sediments but geographically restricted to the Pacific margin, supports this interpretation¹³ (see Fig. 2b).

The Patagonian batholith now lies directly along the Pacific margin of the sedimentary basin. It is a composite,

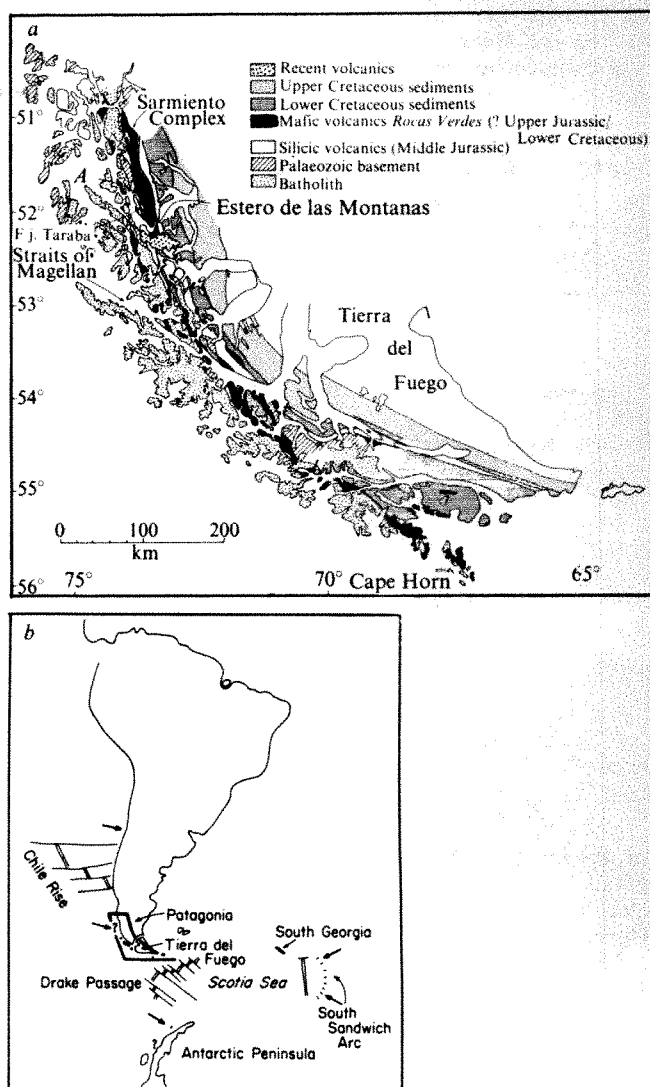

Fig. 1 a, Simplified geological map of the southern Andes, A = Isla Young. b, Location map, arrows show general subduction directions.

and as yet poorly mapped unit consisting of numerous small plutons of coarse grained 'granitic' rocks ranging from tonalite to adamellite. The batholith is intruded into and contains large xenoliths of Palaeozoic metasediments and Late Jurassic silicic volcanics, both readily recognisable as

*Also of Department of Geological Sciences, Columbia University.

†Present address: Churchill College, Cambridge, UK.

parts of the South American continental 'basement' that underlies the Cretaceous shelf sediments to the east (Figs 1 and 2). The Patagonian batholith is strikingly similar to the Peruvian batholith recently described by Cobbing and Pitcher¹⁴.

Hamilton¹⁵ has proposed that large batholiths of intermediate composition, such as those that are more or less continuous along the western North and South American continental margins, are the plutonic equivalents of overlying contemporaneous calc-alkaline volcanic chains. In the southern Andes there is strong support for such a comagmatic origin. Radiometric dating, largely by Rb-Sr whole-rock-mineral isochrons¹⁶, indicates that the batholith was initiated by the Late Jurassic (150 Myr) and that plutonic activity continued intermittently until at least the end of the Cretaceous. Thus it was coeval with the andesitic volcanic activity on the same (Pacific) side of the sedimentary basin.

Thus we conclude that the Patagonian batholith was overlain by an andesitic complex emplaced into South American continental crust, as in the present central Andes, and supplying detritus to the basin on its eastern flank. This then suggests that subduction of the floor of the Pacific Ocean beneath this part of South America was initiated by the late Jurassic.

Marginal basin development

The floor of the basin consists of large lenses (up to at least 120 km long and 20 km wide and more than 2,000

overlap on to these blocks, usually being separated from them by a variable sequence of clastic (often volcanoclastic) sediments including conglomerates, mafic and silicic tuffs, and lavas. The extrusives dip moderately inwards (Fig. 2a). Thus the mafic lenses are funnel shaped in cross section, have normal igneous contacts and are autochthonous.

The sheeted dyke complexes are entirely composed of dykes with chilled margins against each other and basaltic-doleritic textures. They are as much as tens of metres thick but average 1–2 m. Where studied in detail (north of the Straits of Magellan where the Andies trend north-south) they strike consistently subparallel to the Cordillera. Swarms of mafic dykes and gabbro sills are present even outside the main mafic complexes, cutting the rocks of the continental blocks. Where large volumes of these intrusives are present in the continental blocks, especially near the margins of the mafic lenses, remelting and assimilation of the older silicic material is frequently evident. This process has almost certainly resulted in the generation of some of the more silicic phases associated with the gabbros.

Although the original igneous textures are generally preserved in the mafic rocks, the latter generally display zeolite facies mineral assemblages increasing with depth to lower amphibolite facies. At present these assemblages seem to represent an 'ocean floor' type of metamorphism.

The mafic lens we have studied in most detail forms Cordillera Sarmiento north of the Straits of Magellan (Fig. 1). Here the extrusive unit is conformably overlain by fossiliferous sediments dated as Lower Cretaceous (A. Cañon, personal communication). The absence of extensive

Fig. 2 a, Composite east-west section across the Sarmiento complex (for location see Fig. 1) b, Restored diagrammatic section across the southern Andes in the early Cretaceous.

m thick) of mafic rocks (Fig. 1). The lenses are subparallel to the Cordillera. They intrude and separate blocks of Palaeozoic schist and the overlying Middle–Upper Jurassic silicic volcanics (Fig. 2a).

The mafic rocks represent the upper parts of ophiolite assemblages. An intrusive unit, consisting of gabbro that may show cumulative layering, is cut by, and passes upwards into, a sheeted dyke complex. At still higher levels the sheeted complex is overlain by an extrusive unit of considerable thickness consisting of near horizontal pillow lavas, pillow breccias and tuffs. The intrusive–extrusive transition is complex, the dykes thinning and becoming irregular and more widely separated by screens of pillow lavas. Individual dykes frequently feed pillows. The extrusives are in turn overlain by, and intercalated with, minor amounts of chert and jasper.

The intrusive unit has steeply dipping igneous contacts with the continental blocks. In places the extrusive units

flyschlike sediment layers within and below the mafic extrusives suggests that the latter were extruded very rapidly during a major pulse of magmatism in the early Cretaceous and that marginal basin formation was initiated during the evolution of the andesitic volcanic complex along the Pacific continental margin.

The floor of the marginal basin consisted of huge strips of 'oceanic' crust separated by elongate blocks of older continental crust and must have formed by extension and intrusion of basaltic magma behind an active andesitic volcanic chain. Extension moved the volcanic chain towards the Pacific, relative to South America, producing a volcanic island arc based on continental crust and separated from the stable continent by a marginal basin whose floor had geophysical characteristics partly 'oceanic' and partly 'continental'. The geotectonic setting must have been analogous to the present Japan Sea area in these respects. The apparent absence of ultramafic complexes

from the otherwise complete ophiolite suites of the southern Andes may be the result of structural level, because in Cordillera Sarmiento the gabbros are at sea level. The question of whether or not the crust of marginal basins is identical to that of large ocean basins remains, however, to be settled.

Closure of marginal basin

The youngest dated rocks of the basin infilling are Aptian. The whole sedimentary pile, together with the underlying basin floor, shows signs of strong deformation. These tectonic structures are cut by undeformed granodioritic plutons that have been dated as 80–90 Myr old^{16,17}. It is clear, therefore, that the marginal basin rocks were deformed after the Aptian and before the end of Coniacian¹⁸. We consider this deformation to have occurred when the volcanic arc was translated back towards the continental margin. The resultant shortening between the arc and continent caused the deformation not only of the rocks of the marginal basin but also of its margins, particularly the eastern continental margin.

The very varied basin floor assemblages were very inhomogeneously deformed. Zones of intense and locally polyphase deformation alternate with large areas of virtually undeformed rocks across the width of the basin, the areas of high strain often being concentrated along major lithology contrasts. North of the Straits of Magellan the floor rocks of the basin display essentially vertical planar structural elements (shear zones, slaty cleavage and major fold axial surfaces) that parallel the strike of the Cordillera.

By contrast the sedimentary fill of the basin appears to be more uniformly deformed. A persistent, well developed, slaty cleavage that is axial planar to related asymmetric folds occurs throughout the cover sediments, striking parallel to the Cordillera. South of the Straits of Magellan the cleavage and fold axial surfaces dip towards the Pacific. The vergence of the folds towards the Atlantic^{19,20} is accentuated by small thrusts in the anticlinal hinges that translate the rocks in the same direction. This fold vergence is also predominant in southern Tierra del Fuego where the Cordillera trends west-east^{12,19}. Moreover, if recent reconstructions of the North Scotia Ridge are correct^{21,22}, the flyschlike Cumberland Bay and Sandebugten sequences of South Georgia^{23,24} also represent basin fill, and the Cumberland Bay has the same Pacific to Atlantic vergence^{23,24} and is thrust towards the Atlantic over the Sandebugten sequence that has predominantly opposed vergence²⁵.

The rocks to the east of the marginal basin on the South American continental margin of the early Cretaceous show varying intensity of deformation. Along the whole length of the Cordillera the silicic volcanic layer beneath the Cretaceous and Cainozoic sedimentary cover has been structurally uplifted and crops out in a narrow belt along the Atlantic margin of the High Cordillera. In the north deformation of the Palaeozoic basement schists, like that of the mafic lenses, is confined to narrow zones²⁰. In the east–west trending Cordillera in Tierra del Fuego, by contrast, widespread reactivation of the Palaeozoic basement has occurred^{20,26}. Everywhere the intensity of deformation dies away rapidly towards the Atlantic.

The rocks of the volcanic arc itself were also probably deformed at this time. Some narrow subvertical shear zones in the batholith may be related to basin closure. To the north of the Straits of Magellan the Palaeozoic schists into which the batholith was emplaced are deformed in zones as on the eastern margin of the basin.

The basin must have closed by obduction, subduction or internal deformation of the basin floor and its infill, or by a combination of these processes. As the rocks of the basin

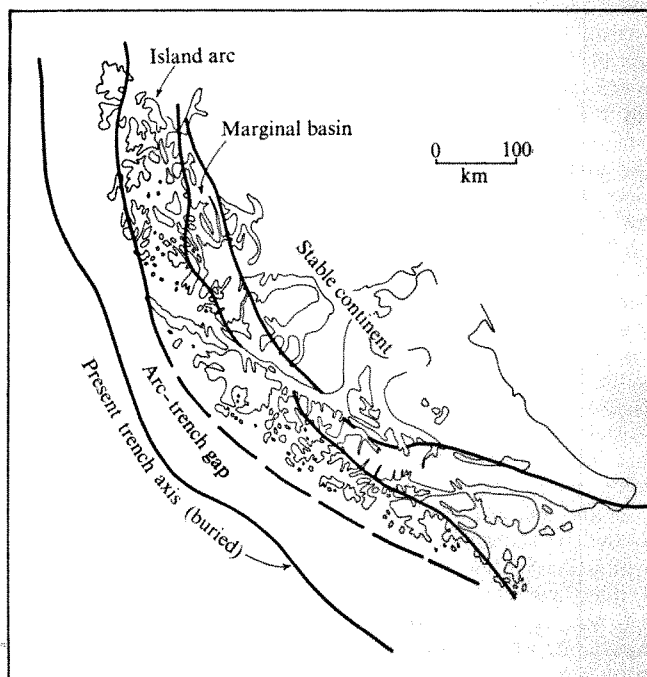

Fig. 3 Present location of the main tectonic divisions of the southern Andes, as interpreted in this paper.

floor appear to be entirely autochthonous, obduction can be rejected. The marginal basin rocks we have studied were certainly horizontally shortened by internal strain. It has not yet been determined whether this resulted from subduction of the basin floor. If subduction occurred the mafic lenses now preserved merely represent relics of the easternmost part of an originally more extensive marginal basin.

Geotectonic implications

Several significant conclusions can be drawn:

(1) There is positive evidence in the southern Andes that the Mesozoic batholith along the Pacific continental margin represents the root of an andesitic volcanic chain that was initiated on South American continental crust by the late Jurassic. We relate the formation of the volcanic chain and its continued activity into the Cretaceous to subduction of the Pacific Ocean floor beneath the South American continent.

(2) In the latest Jurassic–early Cretaceous, basaltic magmas were intruded into the continental crust behind the volcanic complex that was consequently translated towards the Pacific relative to South America, creating a marginal basin between a volcanic island arc and the South American continent. The marginal basin seems to have formed during a single major pulse of rapid extension, and was infilled during the early Cretaceous by andesitic detritus from the active arc. The original width of the basin is not known.

(3) During the middle Cretaceous the arc moved back towards the continent accompanied by the deformation of the basin rocks, the South American continental margin and probably the arc itself. Recognition of the inhomogeneous deformation of the mafic lenses leads us to emphasise that the dating of ocean floor remnants solely on the basis of the presence or absence of deformation fabrics such as has been attempted in the Appalachian/Caledonian orogen^{27,28} must be undertaken with the greatest caution (J. R. Burnsall and M. J. de Wit, in preparation).

(4) Based on fossils in the sediments overlying the mafic

lenses, it can be interpreted that the marginal basin opened before 118 Myr (base of the Barremian). From the age of the plutons cutting the deformed basin infill, it closed before 88 Myr (base of the Coniacian). Thus whereas the opening took place during a period of 'normal' seafloor spreading rates in the Pacific, closure and accompanying deformation coincided with the period of particularly high spreading rates between 110 and 85 Myr ago²⁹.

The opening of the marginal basin took place by extension and intrusion behind the arc, apparently in the manner suggested by Karig³⁰ and Uyeda³¹. Field observations clearly demonstrate that the 'ophiolitic' rocks do not represent old oceanic crust fortuitously trapped between South America and an island arc migrating across the Pacific^{2,6}. Closure of the basin did not take place by obduction of the basin floor. Horizontal shortening was certainly involved and Pacific-ward subduction may have taken place.

In the Central Andes and in West Antarctica ophiolitic rocks are unknown^{10,14,22}, although there is substantial evidence of Mesozoic subduction^{32,33}. Hence it seems that a marginal basin with a mafic or partially mafic floor did not develop in these areas. At least in the central Andes, however, an early Cretaceous sedimentary basin infilled with flysch-type sediments full of andesitic detritus and mafic extrusives, did develop behind the Mesozoic volcanic chain, perhaps indicating more limited extension. Significantly, the mid-Cretaceous deformation there was far less intense and of a different style, consisting of block faulting and gentle warping. Penetrative fabrics are wholly absent. Thus it seems that large penetrative strains at high crustal levels are not generated behind a volcanic arc by subduction alone but may be related to 'collision' between volcanic arcs and continents during closing of marginal basins.

The data show that marginal basins are not characteristic solely of the western side of the Pacific Ocean. They have existed in the past along the eastern margin. Hence the present western South American continental margin is not representative of all Mesozoic-Cainozoic Andean geological history. Recognition of this fact leads us to consider the factors involved in the opening and closing of marginal basins.

Wilson and Burke⁵ have suggested that marginal basin formation is related to the relative motion of lithospheric plates and the mantle underlying the asthenosphere. According to their hypothesis the consuming plate at a subduction zone, such as the American plate at the Peru-Chile trench, if advancing over the lower mantle, will develop no marginal basin. If, however, the over-riding plate is stationary over the mantle or retreating from the plate being consumed, then marginal basins will develop as in the western Pacific.

Scholz *et al.*³⁴ have suggested a more general explanation that marginal basin formation is related to the level of the horizontal component of compressive stress across the consuming plate boundary. An increase in this component could arise from an increase in spreading rate and it may not be a coincidence that the age of closure of the marginal basin in the southern Andes coincides with the world-wide pulse of high spreading rates²⁹. In addition to changes in relative motion of plates over the mantle, increase in spreading rate and certain changes in plate configuration, it has been suggested that marginal basin closure could also result from weakening of the mafic floor of the basin because of high heat flow below an insulating 'blanket' of volcanoclastic sediments. The metamorphic assemblages of the southern Andean mafic lenses could be taken to support this view but the fact that a uniform penetrative fabric is lacking seems to argue against it.

The question of why the basins open and close is at present unresolved, and it is increasingly apparent how crucial the answer is for understanding the evolution of continental margins and mountain belts. Recognition not only that a marginal basin developed in the Andes, but that it opened and closed before those of the present western Pacific were initiated, may be of great significance for understanding of the evolution of continental margin orogenic belts and the history of the Pacific Ocean basin.

The study was mainly supported by the Office of Polar Programs of the National Science Foundation and by the Empresa Nacional del Petroleo de Chile (ENAP). We thank Dr Mort D. Turner, Robert Dale and Robert Elder of the Office of Polar Programs, and to Eduardo Gonzalez P. and Paul Cortés R. of ENAP for their help. Support for some of the work on the Argentine continental margin was provided by a National Science Foundation grant as part of the International Decade of Oceanographic Exploration. One of us (K. F. P.) was the recipient of a NATO Postdoctoral Fellowship from the Natural Environment Research Council of the United Kingdom. We thank A. H. Hynes, W. C. Pitman III, C. H. Scholz and R. A. Schweickert for helpful criticism of the manuscript.

Crystallographic study of the interaction of urea with lysozyme

K. W. Snape, Robert Tjian*, C. C. F. Blake & D. E. Koshland, jun.†

Laboratory of Molecular Biophysics, Department of Zoology, South Parks Road, Oxford OX1 3PS, UK

High-quality crystals suitable for an X-ray crystallographic study have been obtained for urea-denatured lysozyme

As more protein structures become known through the use of crystallographic methods, knowledge of the basic structure, and also of perturbations of the structure will be required to understand the forces involved in the architecture of the proteins and the catalytic power of enzymes. One of the perturbations which may prove useful, is the unfolding of proteins caused by high concentrations of urea. Although many solution probes such as nuclear magnetic resonance (NMR), electron spin resonance (ESR) and fluorescence, have been used in denaturation studies, these tools, powerful as they are, can probe only small portions of the protein at a time. Such a partial picture makes it difficult to relate structure change with activity since only some of the changes are known. A comprehensive recording of all changes could be obtained by crystallography but unfortunately crystallisation of proteins in urea has seemed difficult theoretically or recalcitrant experimentally. It was therefore decided to explore conditions for obtaining enzyme crystals from urea by the manipulation of urea and salt concentrations. This has now been achieved for lysozyme and excellent X-ray diffraction patterns have been obtained from crystals in equilibrium with high urea concentrations.

Preparation of lysozyme crystals

Native, tetragonal crystals of hen egg white lysozyme chloride were grown following the method of Alderton and Fevold¹: 400 mg of lysozyme were dissolved with thorough stirring in 5 ml of 0.04 M acetate buffer pH 4.7 and the stirring was continued for a further hour to dissolve nuclei. Sodium chloride solution (5 ml, 10% w/v) was added dropwise over several minutes, the final solution was filtered into a polythene bottle and left undisturbed for up to two weeks. Crystal nucleation generally occurred within a few hours but growth was regarded as complete only after two weeks had elapsed.

Tetragonal crystals of lysozyme were crystallised with, for example, 6 M urea by a simple variation of the above procedure: 300 mg of lysozyme were dissolved in 2 ml of a solution which was 4 M in acetate buffer pH 4.7, and 9 M in urea. After equilibrium (assumed to be up to 1 h), 1 ml of saturated sodium chloride solution was added and after further gentle stirring the solution was filtered and left. Nucleation and growth of the crystals was generally as rapid as for the native crystals.

Equilibration of native lysozyme crystals with urea solutions was achieved by first stabilising the crystals with a solution of 0.2 M acetate buffer, 12.3% w/v NaCl and subsequently with solutions of the same salt content but

with the appropriate urea concentration. Equilibration was achieved by adding the final stabilising solution dropwise over several days, with gentle agitation at each addition, to the crystals in their original mother liquor.

Hen egg white lysozyme (3X-crystallised, dialysed and lyophilised), Lot 70C 8110, and N-acetyl glucosamine (NAG) (Sigma (London) Chemical Co.), Tri-N-acetylchitotriose (tri-NAG) and analytical grades of urea, glacial acetic acid, sodium acetate trihydrate and sodium chloride

(British Drug Houses, Ltd) were used. The urea was freshly recrystallised from glass distilled water immediately before use and only freshly prepared urea solutions were used. Screened precession photographs (18°) of the (centric) HKO and HOL zones were obtained using Ni-filtered copper radiation from an Elliott Automation rotating anode, Type GX3. Photographic intensities were estimated using a Joyce-Loebl double-beam recording microdensitometer Mark III CS. Crystals were conventionally mounted and sealed in contact with the vapours of their respective equilibrium soaking solutions.

Isomorphism of crystals

Crystals of hen egg white lysozyme in equilibrium with solutions of urea show diffraction patterns indicating isomorphism with native crystals². Significant alterations in the intensities of reflections were observed without any loss of order in the crystals or any large change in cell dimensions (compare Fig. 1). The detailed X-ray crystallography therefore confirmed the qualitative observation that good crystals existed in the urea plus salt mixture and that the

crystals give X-ray patterns of the same quality as do the native crystals.

Examination of the photographs (of which Figs 1 and 3 include two representative examples) shows large intensity changes in many of the reflections. These intensity changes indicate that urea causes extensive structural alterations without any resultant loss of crystallinity. This clearly allows a structural investigation of the lysozyme molecule in high concentrations of urea to be carried out using X-ray techniques. Extensive studies of lysozyme structure and activity in urea solutions have been made³⁻¹¹, which have indicated that the lysozyme structure is generally rather resistant to denaturation by urea but that changes do occur. X-ray crystallography confirms these findings in general but allows more specific conclusions to be made. Edelhoch and Steiner⁵, for example, found that the molecule retained some structure, that is, was not a random coil, even in 9 M urea. The X-ray results are in agreement with this conclusion and indicate a surprising degree of order for a solvent of such denaturing capacity.

The changes in intensity are unfortunately much too great (compare Fig. 1) for a conventional difference synthesis against the known native structure to be useful in defining the precise nature of the changes induced by urea. In these circumstances there is no alternative to a complete *de novo* structure determination of the denatured molecule, and a search for useful heavy-atom derivatives has been started. Some useful information of a general nature can, however, be deduced from the intensity changes. The alterations in intensity are particularly pronounced at high resolution, indicating that changes occur largely to the detailed structure of the molecule. A three-dimensional difference map between the 3 M urea and native forms, using terms to 3 Å resolution, while confirming our judgement that the intensity changes were too extensive to be useful in detail, showed that the major difference density features were confined within the molecular envelope. This indicates that while some contribution to the intensity changes can probably be expected from perturbation of the solvent structure, it is clear that the major contribution arises from conformational changes distributed throughout the molecule itself.

Variation with urea concentration

Preliminary phase information from the heavy-atom search together with an analysis of the variation of X-ray intensities as a function of urea concentration allow some broad but definite inferences to be made about the lysozyme-urea system under study. An examination of precession photographs extending to 2.5 Å resolution shows that the intensities of a majority of the centric HKO and HOL reflections vary in a monotonic manner. The detailed intensity variations of a small number of representative medium-resolution reflections are shown in Fig. 2*a*, and a plot of the structure factors of the best phased reflections in this group in Fig. 2*b*. Figure 2 shows that the major changes in intensity have occurred by the time the concentration of urea has reached 3 M, and that the further changes up to 9 M are small. This suggests that the major conformational changes induced by the urea have occurred at these low concentrations, and that thereafter further alterations are minor.

A small number of reflections seem to behave in a different way. Their intensities first decrease to zero as the urea concentration increases and then subsequently increase at higher concentrations. The preliminary phase information indicates, however, that the reflections behaving in this way have all undergone a change of sign (see, for example, 13, 16, 0 in Fig. 2*a* and *b*) and when this factor is taken into account, all the reflections examined are found to vary monotonically. The finding of such

monotonic changes in the diffraction pattern might indicate a two-state denaturation model, or at least be consistent with such a model. But, the knowledge of protein structure which already exists, and the failure of two-state models to account for the kinetics of either denaturation^{12,13} or refolding^{14,15} suggests that such a model is unlikely, and indeed a plot of fractional structure factor changes as a function of urea concentration for individual reflections gave differing curves indicating deviations from a mutually linear relationship. Additional small intensity changes due to the minor concentration-dependent changes in cell dimensions cannot be corrected for, however, and these data *per se* cannot exclude a two-state model. It is, of course, conceivable that, because we are dealing with the structure in a crystal, there are certain constraining relationships which favour an apparent two-state model. A definitive answer to this problem must await the complete three-dimensional crystallographic study which is now in progress.

Stability of the protein

A particularly interesting feature of this X-ray study is the thermodynamic stability both of the protein and of the tetragonal crystal form. Changes in the diffraction patterns seemed to be complete within 24 h of the introduction of urea, suggesting a rapid attainment of equilibrium, but there were no further changes when the crystals were subsequently exposed to the urea solutions for a period of weeks. Crystals equilibrated with high urea concentrations could, in addition, be leached with urea-free high salt solutions and were found within 24 h to regain in full their original native diffraction patterns. That this stability represents a true thermodynamic minimum was demonstrated by the crystallisation of lysozyme directly from urea solutions. Crystals obtained from 1 M urea had diffraction patterns which were identical to those of soaked crystals, whereas those obtained from 6 M urea showed only minor high-angle differences when compared with their corresponding soaked crystals (compare Fig. 3). This retention of isomorphism is especially interesting in view of the appreciable conformational changes indicated both by physical studies and by the present work, and confirms that the basic form and packing of the molecules is not altered as much as might be expected.

No glutaraldehyde or other cross-linking material has been used to cross-link the crystals. The main feature that has changed the urea from a medium which dissolves protein to one in which crystals are stable is the use of high salt concentrations.

While this work was in progress, we learned of the study of Berthou and Jolles¹⁶ who have also crystallised lysozyme from urea. Their studies on temperature effects and polymorphism should offer additional valuable insights into lysozyme properties.

Further uses

In summary, these studies indicate that crystallisation of proteins from urea is possible and that the X-ray crystallography of these structures will be valuable in interpreting the role of conformation in the activity and folding of proteins. The use of urea for structural changes has considerable advantages in studying protein structure since it is the differences rather than the creation of a total structure that is being dealt with. Furthermore, the use of lower concentrations of urea can in some cases produce smaller perturbations of structure. We hope that further work will relate conformational changes to the activity of the lysozyme. Preliminary (unpublished) results indicate that activity is regained and conformational changes are induced when polysaccharides are added.

X-ray crystallography is particularly valuable for such structure-activity correlations. The examination of any

one group, such as by using reporter groups is useful, but the role of a residue may be ambiguous if the perturbations of other groups are not known. Crystallography gives an overall three-dimensional picture which would be difficult or impossible to achieve with individual probes, but is also more time consuming. Eventually parallel relationships in which the probing of an individual group by a reporter group can be correlated with key X-ray structures may offer the complementary advantages of completeness and economy of effort. Our present X-ray results with lysozyme make possible such interrelated studies.

The generality of the method is supported by unpublished studies on chymotrypsin which have shown that it can be crystallised from 6 M urea and remain isomorphous with the native enzyme. Thus, the results found here in relation to lysozyme can be applied to a variety, possibly a majority, of protein molecules.

Plate movement relative to rigid lower mantle

L. Lliboutry

Department of Geophysics, Grenoble University I and Laboratoire de Glaciologie du CNRS, Grenoble, France

The vertical extent of the flow in the upper mantle may be governed by the layering of the Earth, with the lower mantle rigid enough to act as a frame of reference. A theorem deduced from basic mechanics gives the movement of the plates relative to this frame. The fit with velocities deduced from the migration of deep volcanism is excellent. Absolute velocities of trenches may be related to the slope of the sinking slabs of lithosphere.

THERE have been several successive steps in the hot spot theory¹. It was first suggested that volcanic chains of the Hawaiian type are produced by hot spots deep in the mantle. Then came the suggestion that the hot spots form a consistent frame of reference. If this were so, then at a particular depth, the bulk of the mantle outside the hot plumes should be subject to shrinking at a negligible rate only. Furthermore, horizontal movements should be confined within the upper mantle and near to the mantle-core interface. The third suggestion was that hot spots could also provide the motive force for continental drift, with horizontal currents in the asthenosphere flowing radially away from each of the plumes. I here deal with the first two suggestions, but do not consider the third idea which is much more controversial.

The movement of the lithospheric plates relative to the lower mantle can be deduced directly, using basic mechanics, as long as the model fits some general conditions. The fit between the relevant calculations supports the validity of the model used.

Necessary assumptions

I assume that the lower mantle, below the 700 km discontinuity, is rigid enough away from hot plumes, to be taken as a frame of reference. Velocities relative to this frame will be termed 'absolute velocities'.

This assumption conflicts with some questionable estimations of the viscosity at depth. McConnell's method of calculating velocities from the profiles of raised beaches² gives no pertinent information about regions below 800 km. Although Goldreich and Toomre³ have explained the nonhydrostatic bulge of the Earth by assuming a mean viscosity $< 10^{24}$ poise, an earlier explanation⁴, which suggested a mean viscosity $\approx 10^{26}$ poise has not been disproved. A mean viscosity of 10^{23} poise at the

mantle-core interface, with a shear strain rate of 10^{-16} s^{-1} has been calculated⁵. It is, however, the shear stress, not the shear strain rate, which is spread over the whole mantle with the same order of magnitude (for instance 5-10 bar), with convection, or without it. With such a shear stress in the asthenosphere, where the melting point is reached, Weertman's law⁶ would give a shear strain rate of 10^{-8} to 10^{-9} s^{-1} , a value 10^6 times too high. By modifying the numerical factor accordingly, the viscosity at the mantle-core interface rises to 10^{27} poise.

My second assumption is that, with the exception of hot plumes and descending slabs, there are no lateral variations in the viscosity of the upper mantle. A three-layer model can be adopted. The top layer is composed of rigid lithospheric plates, which may be limited downwards at an isobaric surface p_0 without substantially changing the dynamical problem. Under this is a low viscosity layer (for instance 4×10^{20} poise). The bottom layer is more viscous (for instance 10^{22} poise), and is of uniform thickness and horizontal extent. The viscosities of layers 2 and 3 are assumed to be Newtonian for the very slow motions involved.

My third assumption is that the viscous layers have densities ρ_1 and ρ_2 , respectively, with horizontal variations which are much larger than the vertical variations within a single layer. The horizontal variations are a function of temperature changes which are governed by the convection processes, and so this assumption implies that any reversal of the current should occur near an interface between layers.

Absolute velocities

Departures from the hydrostatic values are here termed 'perturbations'. The equations of quasistatic equilibrium and of viscosity can be written in a linear form with respect to the perturbations. This is not so, however, with the heat equation, because the convective term in $\mathbf{u} \cdot \nabla T$ is the main one; thus it is not introduced, and the horizontal density gradients $\nabla \rho_1$ and $\nabla \rho_2$ are considered as unknown functions.

I have shown⁶ that, in the two-dimensional case, any perturbation may be expressed as a linear function of four perturbations. With the x -axis horizontal, the velocity $u_{0,x}$ at any point on a plate may be written:

$$u_{0,x} = C_1 \partial \zeta / \partial x + C_2 \partial \rho_1 / \partial x + C_3 \partial \rho_2 / \partial x + C_4 \tau_{2,x} \quad (1)$$

where ζ denotes the vertical deflection of the isobaric surface p_0 and $\tau_{2,x}$ is the shear stress, in the x direction, between the

third layer and the motionless lower mantle. C_i is constant (for a given model) independent of the perturbations. Equation (1) holds to the second order only, but because with reduced variables C_i is of the order of unity and the perturbations are of the order of 10^{-3} – 10^{-4} , this inaccuracy is of little concern.

In the three-dimensional case, equation (1) holds in the x direction, and in a transverse horizontal direction (substituting y for x) because, to the second order, the perturbations in the x and y directions do not interfere with one another. Therefore:

$$\mathbf{u}\partial = C_1\nabla\zeta + C_2\nabla\rho_1 + C_3\nabla\rho_2 + C_4\tau_2 \quad (2)$$

According to my third assumption, equation (2) is valid over the whole Earth with the same constants C_i , with the exception of some small areas (oceanic ridges, subduction zones, and so on). Of course, for points on one plate the values of \mathbf{u}_0 are linked and thus the four vectors on the right hand side of the equation are not independent. When crossing a ridge or a subduction zone, ζ does not undergo a discontinuity. The same is true, to the second order, for ρ_1 and ρ_2 , as the conditions are very close to hydrostatic.

(It should be noted that the nullity of the total mass transport through the three layers is not introduced, as was the case in previous articles^{6,7}. Even if there were no hot plumes rising from the lower mantle, this nullity would hold only in the two-dimensional case, that is for a 'cylindrical Earth'. This point will be developed elsewhere.)

There can be a horizontal vector, \mathbf{a} , defined at any point on the Earth's surface. The resulting moment of $\mathbf{a}dS$ over the whole Earth, with respect to an arbitrary diameter DD' is

$$\iint (\mathbf{OD} \times \mathbf{OM}) \cdot \mathbf{a} dS = \mathbf{OD} \cdot \iint (\mathbf{OM} \times \mathbf{a}) dS \quad (3)$$

(taking the radius of the Earth, OM , as unity of length). This quantity vanishes when, and only when:

$$\mathcal{M}_0(\mathbf{a}) \equiv \iint (\mathbf{OM} \times \mathbf{a}) dS = 0 \quad (4)$$

It can easily be shown that, when \mathbf{a} is the gradient of a function continuous over the whole Earth, $\mathcal{M}_0(\mathbf{a}) = 0$

Such is the case for ζ , ρ_1 , ρ_2 , and thus:

$$\mathcal{M}_0(\nabla\zeta) = \mathcal{M}_0(\nabla\rho_1) = \mathcal{M}_0(\nabla\rho_2) = 0 \quad (5)$$

Moreover, as the rigid lower mantle is assumed to be spherical, the quasistatic equilibrium of the whole system means that $\mathcal{M}_0(\tau_2) = 0$. Thus, according to equation (2)

$$\mathcal{M}_0(\mathbf{u}_0) = \iint (\mathbf{OM} \times \mathbf{u}_0) dS = 0 \quad (6)$$

For any closed path drawn on a single plate, the conservation of mass requires,

$$\oint (\mathbf{OM} \times \mathbf{u}_0) ds = 0 \quad (7)$$

where ds is an infinitesimal arc.

As this relationship no longer holds when the path crosses a ridge or a trench, equation (6) is important.

Ω is the instantaneous rotation vector of the plate at point M , and, relative to the lower mantle, $\mathbf{u}_0 = \Omega \times \mathbf{OM}$. Equation (6) can thus be written

$$\iint (\mathbf{OM} \times \Omega \times \mathbf{OM}) dS = \iint \Omega dS - \iint \mathbf{OM} \cdot (\Omega \cdot \mathbf{OM}) dS = 0 \quad (8)$$

Ω is different from plate to plate.

In Cartesian coordinates, with the origin at the Earth's centre O , the components of \mathbf{OM} are x , y , z , and of Ω : Ω_x , Ω_y , Ω_z . Equation (8) becomes:

$$\iint \Omega_x dS - \iint x(x\Omega_x + y\Omega_y + z\Omega_z) dS = \iint (y^2 + z^2) \Omega_z dS - \iint x(y\Omega_y + z\Omega_z) dS = 0 \quad (9)$$

with two other similar relationships obtained with permutations of x , y , and z .

ω of components ω_x , ω_y , ω_z , can be the rotation vector of any plate relative to a reference plate (the Antarctic plate in these computations), and Ω_0 , of components a , b , c can be the 'absolute' rotation vector of the reference plate. Then:

$$\Omega_x = \omega_x + a \quad \Omega_y = \omega_y + b \quad \Omega_z = \omega_z + c \quad (10)$$

As:

$$\iint xy dS = \iint xz dS = 0 \\ \iint (y^2 + z^2) dS = 8\pi/3 \quad (11)$$

it follows that:

$$a = -3/8\pi \iint (y^2 + z^2) \omega_x dS \\ + 3/8\pi \iint x(y\omega_y + z\omega_z) dS \quad (12)$$

with two similar relationships for b and c , obtained by permuting x , y , and z .

Comparison with former estimations and results

In an earlier publication⁷ the two-dimensional relationship of equation (1) has been extended to cover the whole Earth. Only the plates of the equatorial zone were considered, and the effect of other plates was neglected. That is a very crude model of a 'cylindrical Earth'. This procedure was equivalent to neglecting the second integral on the right hand side of equation (12). If there were a very large number of plates, with random rotation vectors, this second integral should in fact vanish.

McKenzie⁸ has suggested that the term 'polar wandering', which described the motion of the pole relative to a frame of reference, should be defined such that

$$\iint \Omega dS = 0 \quad (13)$$

In other words, he defines 'absolute' velocities of continental drift by:

$$a = -1/S \iint \omega_x dS \quad (14)$$

To study of the causes of polar wandering it seems preferable to use equation (12) instead. 'Polar wandering' would then be the motion of the pole relative to the bulk of the mantle, excluding its outer viscous shell, that is, relative to the rigid body which carries most of the Earth's momentum. It follows from equation (7) that both definitions would be identical if $\mathbf{OM} \cdot \Omega \approx 0$ for all of the plates. This, however, is not the case.

The computation has been done using Chase's determination of the relative rotation vectors⁹, which takes into account the velocities at the ridges (deduced from the magnetic lineations of the ocean floor) and the direction of the transform faults, but which does not use data on the migration of volcanism (which may then be used as an independent check). To render the integrals discrete, the Earth's surface has been divided into bands of 5° of latitude, and for each band the boundaries between the plates have been located to within 1° of longitude.

Table 1 gives the 'absolute' rotation vector of the Antarctic plate according to McKenzie's definition (equation 14), to the two-dimensional approximation, and to my present theory (equation 12). The differences are not negligible. Table 2 gives the relative rotation vectors calculated from Chase's data, and the absolute rotation vectors according to my present theory.

It seems that the South American plate, because it has a pole of rotation on itself, and the Antarctic plate, because it has a pole of rotation very near itself, are almost motionless. (Some symmetrical, eastward motions are occurring in Patagonia and the Antarctic Peninsula. These increase towards the Drake Passage.) Africa and the Indian Plate are moving towards the north-east, Europe towards the east, Indochina and Indonesia towards the south-east, and Alaska towards the south. This asymmetry of absolute motions on both sides of the Pacific Ocean may be related to the asymmetry in the slope of the descending slab¹⁰. Any descending slab should have a tendency to sink vertically downwards under its own weight. Nevertheless, if the trench is moving towards the ocean, the horizontal velocity of the trench must be added to the vertical velocity, to give the slope of the slab. This should be the case on the western side of the Pacific Ocean. There, the absolute velocity of the Eurasian plate, and the extension of the marginal seas (which has its own causes), add together to give a large eastward absolute movement of the Japanese–Kuril Trench. Thus, the sinking slab under the Japanese sea has a uniform slope of 30° until its very end, at a depth of 600 km whereas the lower end of the sinking slab under South America is almost vertical.

Comparison with migration of volcanism

If λ_p and ϕ_p are the latitude and longitude, respectively, of a pole of absolute rotation, then its distance, γ , from a point, λ , ϕ , in the corresponding plate is given by the relationship:

$$\cos \gamma = \cos \lambda \cos \lambda_p \cos (\phi - \phi_p) + \sin \lambda \sin \lambda_p \quad (15)$$

The absolute velocity, u_0 , at (λ, ϕ) is then

$$u_0 = (10/9) \Omega \sin \gamma \text{ cm yr}^{-1} \quad (16)$$

where Ω is expressed in 10^{-7} degree yr $^{-1}$

The azimuth (angle with the meridian) A is given by:

$$\cos A = (\Omega_x \sin \phi - \Omega_y \cos \phi) / \Omega \sin \gamma \quad (17)$$

For the Hawaiian chain, $u_0 = 7.6 \text{ cm yr}^{-1}$, $A = 63^\circ 1/2$, and for the Toubouai Islands (Austral chain), $u_0 = 7.7 \text{ cm yr}^{-1}$, $A = 65^\circ 1/4$. These values may be compared with those deduced from the hot spot theory¹¹. The azimuths are correct to less than 1° , and the velocities are within the limits of confidence.

According to our theory, the absolute motion of the Cocos Plate at the Galapagos Islands is 11.4 cm yr^{-1} ($A = 48^\circ 3/4$), and the absolute motion of the Nazca Plate at the same point is 7.1 cm yr^{-1} ($A = 71^\circ 3/4$). According to Johnson and Lowrie¹², the Galapagos hot spot is generating the Cocos and Carnegie Ridges. Our azimuths coincide exactly with the Cocos and the Malpelo Ridges. This is consistent with the idea that the Malpelo Ridge was formed in former times by the Galapagos hot spot on the Nazca Plate, to become extinct when the boundary between both plates, migrating northwards, crossed the ridge. The Carnegie Ridge would be a distinct feature, probably an extinct ridge like the Alpha Cordillera of the Arctic Basin.

The Walvis Ridge is composite, and does not present a clearcut migration of volcanism¹³. Nevertheless, my theory provides a correct azimuth for its southern part (55° ; $u_z = 4.4 \text{ cm yr}^{-1}$).

Lastly, Duncan *et al.*¹⁴ have discussed the migration of volcanism in central Europe. Using my theory the absolute motion at its western extremity (the Eifel), is 2.4 cm yr^{-1} ($A = 65^\circ$). This velocity is exactly the same as that given by the migration of volcanism, but the direction is consistent with that at the western tip of the volcanic range only. But the central European volcanics do not lie on a straight line, and the opening of the Atlantic may have seriously changed the plate motion in the past, and so the fit is satisfactory.

Thus, for five plates out of eight, in the instances in which, a check is possible, the absolute movement deduced from our theorem is consistent with that deduced from the migration of volcanism. This cannot be mere coincidence, and strengthens the idea that our assumptions are sound: there are no lateral variations in the viscosity (except in a few anomalous areas), and the lower mantle is rigid enough to act as a frame of reference for plate motions. This means that in the future, the determination of absolute velocities could have two important uses. First, they can be used to distinguish recently active volcanic chains which are created by hot spots, in the lower mantle, from other volcanic chains. Second, they could be used to calculate movements in the asthenosphere near sinking slabs and marginal basins, taking into account the absolute velocity of the trench relative to the rigid lower mantle. Such a calculation has never been done so far.

I thank Miss Discrezenzo for computing the integrals giving Ω_0 . Discussions with colleagues have helped to improve the presentation.

Structure of yeast phosphoglycerate mutase

J. W. Campbell, H. C. Watson & Gail I. Hodgson

Molecular Enzymology Laboratory, Department of Biochemistry, University of Bristol, Bristol BS8 1TD, UK

A 3.5 Å resolution electron density map of yeast phosphoglycerate mutase has been calculated which shows that much of the tertiary structure of this enzyme resembles that found in a number of nucleotide binding enzymes although the mutase itself has no known nucleotide binding requirement.

THE extension of the three-dimensional study of the structure of yeast phosphoglycerate mutase (PGM) by X-ray diffraction to 3.5 Å resolution gives us the first opportunity to report some of the structural details of a 'mutase' enzyme. Rather unexpectedly we find that the most striking structural feature of the enzyme resembles that found in certain enzymes which bind nucleotides¹⁻⁷. The phosphoglycerate mutase reaction,

3-phosphoglycerate \rightleftharpoons 2-phosphoglycerate, uses the cofactor 2,3-diphosphoglycerate and has no apparent nucleotide requirement. The results of the present study could therefore provide an important clue in the puzzle of enzyme evolution or alternatively strike a note of caution against over interpretation of results where structural similarities are involved.

Structure determination

The reflection data were measured, in four shells of increasing resolution, on a computer-controlled four-circle diffractometer. The potassium mercuriiodide derivative used in our earlier studies⁸ has now been replaced by a potassium chloroplatinite (5 mM) complex. This new derivative showed better isomorphism than the mercuriiodide derivative though in two experiments it was observed that, after a crystal had been exposed to X-radiation for about 60 h, there seemed to be a rapid and substantial change in the cell parameters. The relevant parameters for the new

derivative are included in Table 1 which summarises the 3.5 Å resolution refinement results. Anomalous dispersion data were measured for both the $K_3UO_2F_6$ and K_3PtCl_4 derivatives. Since our earlier paper we have redefined the origin of the unit cell to coincide with the molecular centre of the tetramer. Independent phase refinement was carried out for each of the four resolution shells of reflections, cycles of maximum probability phase refinement being alternated with the least squares refinement of the heavy atom parameters⁹. The four sets of phased reflections were scaled together using reflections, measured from a single crystal, covering the complete resolution range to 3.5 Å. An electron density map was calculated using centroid phases for nearly 8,000 reflections (average figure of merit 0.80) and plotted on perspex sheets, stacked perpendicular to the crystallographic two-fold axis, on a scale of 0.5 cm per Å.

Fig. 1 Part of the yeast phosphoglycerate mutase 3.5 Å electron density map sectioned normal to one of the local molecular two-fold axes. The other local two-fold axis relates subunits I and II, and Ia and IIa respectively. The direction of the crystallographic two-fold axis, Y, is also indicated.

Electron density map

Detailed visual inspection of the averaged and normal electron density maps showed no significant differences between the two subunits within one asymmetric unit, thus confirming the 222 symmetry of the PGM tetramer indicated in the previous structural work on the enzyme^{8,10}. Part of the electron density map showing the local two-fold symmetry is reproduced in Fig. 1. The fact that the two non-crystallographically related but chemically equivalent¹¹ subunits have apparently identical conformations gives us confidence in the accuracy of the structure determination and also indicates that the conformation of the subunit is stable and not unduly influenced by intermolecular forces within the crystal.

The subunits were named as shown in Fig. 1 with I and II being a pair of subunits in an asymmetric unit and with

Fig. 2 Schematic representation of the structure of yeast phosphoglycerate mutase showing its regions of secondary structure. These regions are numbered from the N-terminal end of the polypeptide chain with A1-A6 being α -helices, B1-B6 being strands of the β -pleated sheet and L1-L4 being surface loops. The extent of each element of secondary structure can be calculated from the residue numbers marked on the figure. The area enclosed by the broken circle indicates the proposed region for the active site of the enzyme.

Ia and IIa being related to them by the crystallographic two-fold axis. A reasonable course was followed for the polypeptide chain throughout subunit II. In the few places where the interpretation of the map required that the polypeptide chain had to bridge a small gap in the electron density, it was usually found that the density in the map associated with the corresponding point in subunit I was continuous. The interpretation of the electron density map for subunit II fitted equally well the density associated with subunit I apart from small regions near the chain termini. These are at the surface of the molecule where, in general, the electron density is slightly less well defined than for the interior of the molecule. There is no suggestion, however, that the conformations of the subunits are fundamentally different.

The positions of many side chains were clearly visible in the electron density map and this information was used to determine the probable chain direction in all major helical regions. In each case the direction was consistent with the interpretation of the map based merely on the continuity of the electron density. Throughout the map, coloured markers were placed on the probable α -carbon atom positions indicating a total of 220 residues, some 30 less than has been predicted for this enzyme subunit based on molecular weight and amino acid composition data¹². Although a number of forms of the enzyme have been reported^{13,14} in which up to nine residues have been removed from the subunit by autolysis, the present crystallographic result would suggest that the molecular weight may be

slightly lower than 110,700.

In yeast PGM there are six strands forming a β -pleated sheet. The first four strands encountered when tracing the chain from the amino terminus are all parallel and the remaining two strands form an antiparallel pair (Fig. 2). There are five α -helical regions flanking the pleated sheet region (Fig. 3a, b) and, in addition, a further α -helical region making six in all. These α -helices together with helical segments in the regions 11-15 and 108-113 (Fig. 2) account for some 80 residues which, when taken with the 27 or so residues contained in the β -pleated sheet region, indicate that almost half the residues in the molecule are involved in some form of major secondary structure.

The contact between the mutase subunits related by the crystallographic two-fold axis is not very extensive involving mostly the loop L3 (for nomenclature see Fig. 2) from each subunit and the helix A5. The contact between the subunits I and II is much more extensive and involves the side chains of helix A2, the main chain leading into helix A2 and the main chain coming out from this helix which also forms one edge of the β -pleated sheet. The quaternary structure of yeast PGM is illustrated in Fig. 4.

Fig. 3 a, Complete mutase subunit in which strands of the β -pleated sheet have been emphasised as thick shaded lines and in which the α -helices on either side of the β -pleated sheet have been drawn with thick black lines. b, First 185 residues of the mutase subunit drawn in a simplified manner to illustrate the chain folding within this region of the subunit. The helices are labelled using the nomenclature defined in Fig. 2. c, First 165 residues of the lactate dehydrogenase structure drawn for comparison with the mutase subunit in a. The coordinates used in preparing this drawing were from Adams *et al.*¹⁷. d, First 150 residues of LDH drawn diagrammatically for comparison with the part of PGM illustrated in b. The helices are labelled using the nomenclature of Rossmann *et al.*^{1,2}.

Fig. 4 A stereographic drawing of the yeast phosphoglycerate mutase tetramer. All four subunits are drawn as being identical. The view is chosen to give as clear a picture as possible of the inter-subunit contacts.

Mutase structure

In the absence of primary sequence data and conclusive substrate binding work the most interesting result of the current study is the striking resemblance that part of the mutase structure seems to bear to a structural feature found in the dehydrogenases¹⁻³ and the kinases^{6,7} in which a region of β -pleated sheet flanked by α -helices seems to have a common folding pattern. Detailed comparison (Fig. 3) of part of the mutase structure (the first 185 residues involving the first four parallel strands of the β -sheet and helices A1-A6) and part of LDH (the first 150 residues involving the first five parallel strands of the β -sheet and helices α B- α F) suggests that the similarity is more than superficial as evidenced by the fact that the helices A1, A2, A4, A5 and A6 of PGM are connected in the same order along the polypeptide chain as the corresponding helices in LDH. There are however significant differences, namely that, in the region described, PGM has one less strand in the β -sheet and the order of the strands in the sheet is not the same. We cannot see how the present electron density map can be reinterpreted to give the exact LDH folding but it is nevertheless quite possible that the mutase folding, as reported here, has evolved from a protein with LDH folding. The change would have resulted from the insertion of a loop of about 35 residues in a position near strand BD causing this strand to be disrupted from the β -sheet with the consequent rearrangement of two of the remaining strands as shown in Fig. 5.

It is also interesting to note that the substrate binding region tentatively proposed for the mutase in our earlier

paper⁸ is in a closely similar position relative to the α - β structure as that found for the nucleotide substrates of both the kinases and dehydrogenases¹⁻⁷.

Evolutionary significance

It has been suggested^{15,16} that the α - β structure, observed first in the dehydrogenases and more recently in the kinases, is a common feature of these enzymes relating their nucleotide binding function. The presence of a similar feature in the mutase, where no nucleotide binding is required, suggests that this particular structural feature is an easily formed stable conformation which could serve as a suitable core for building intracellular enzymes but may also reflect an ancestral gene from which enzymes in one or a group of related biochemical pathways have evolved.

Effects of succinyl-con A on the growth of normal and transformed cells

Ian S. Trowbridge & David A. Hilborn

The Armand Hammer Center for Cancer Biology, The Salk Institute, P.O. Box 1809, San Diego, California 92112

Covering con A binding sites on virally transformed mouse fibroblasts with succinyl con A has no significant effect on their growth pattern.

CULTURED mouse 3T3 fibroblasts and their viral transformants, SV40-transformed 3T3 (SV3T3) and polyoma-transformed 3T3 (Py3T3) cells, serve as models to demonstrate the differences in growth control between normal and malignant cells^{1,2}. Under normal culture conditions the growth of 3T3 cells and SV3T3 cells is controlled by serum growth factors^{3,4}. As these factors become exhausted, 3T3 cells stop growing and arrest in the G₁ phase of the cell cycle without loss of viability⁵. Under identical conditions SV3T3 cells grow to a much higher cell density than 3T3 cells⁶ as a result of a reduced serum requirement⁷. SV3T3 cells do not arrest in the G₁ phase as serum factors are depleted. Instead they continue to grow, moving slowly through all stages of the cell cycle before they eventually die^{8,9}.

Table 1 Minimum concentration of lectin required for agglutination of cells

Cells	Lectin concentrations ($\mu\text{g ml}^{-1}$)	
	Succinyl con A	Con A
SV3T3	250	10
3T3	>1,000	50

Cells were removed from the dishes by successive washes with 0.15 M NaCl-0.01 M sodium phosphate pH 7.2 (PBS) and with PBS containing 5×10^{-6} M EDTA, followed by a 10 min incubation at 37° C in PBS containing 5×10^{-5} M EDTA²⁶. The cell suspension was washed once with PBS and the cells resuspended at 2×10^6 cells ml⁻¹. Agglutination assays were performed in Linbro 16 mm multi-well tissue culture plates²⁷. Cells (0.2 ml) were mixed with lectin (0.2 ml) and the trays placed on a rotary table²⁸ (1-2 Hz) for 20 min at room temperature. Agglutination was estimated using an inverted light microscope.

It is possible that changes in the cell membrane are responsible for malignant growth¹⁰⁻¹². Recently it was reported that Py3T3 cells grown in the presence of trypsinised concanavalin A (con A) revert to normal growth¹³. Native con A is a plant lectin which binds terminal α -D-glucosyl and α -D-mannosyl sugar residues^{14,15}, and it was suggested that the binding of trypsinised con A to glycoproteins on the surfaces of Py3T3 cells caused the reversion to normal growth.

Although originally described as monovalent, subsequent characterisation has shown that protease-treated con A is a complex mixture which includes unmodified protein and totally inactive digest products¹⁶. The complexity of trypsinised con A makes analysis of its biological effects difficult. Extensive succinylation of con A converts the native tetrameric molecule to a dimer with the same binding affinity as the native molecule for methyl α -D-glucoside¹⁷. Succinyl con A is less toxic than the native lectin and does not readily agglutinate cells^{17,18}. Because succinyl con A has a low toxicity but has a similar binding specificity to that of the native lectin, we tested its effects on the growth of normal and transformed cells.

Agglutination and lectin binding

Agglutination studies and lectin binding assays were performed with succinyl con A to find conditions under which the con A binding sites on the cell surface of SV3T3 cells could be covered without inducing cell agglutination. Twice crystallised con A (Miles-Yeda, Kankakee, Illinois) was used without further purification; succinyl con A was prepared and characterised as described¹⁷. Cells from confluent cultures of 3T3 and SV3T3 cells were used in the agglutination assays and the specificity of the lectin-induced agglutination was demonstrated by the inhibition of agglutination by 100 mM methyl α -D-mannoside. Though con A agglutinated SV3T3 cells at a concentration of about $10 \mu\text{g ml}^{-1}$, the concentration of succinyl con A required to give detectable agglutination was about $250 \mu\text{g ml}^{-1}$ (Table 1). Succinyl con A at 1 mg ml^{-1} did not agglutinate 3T3 cells.

The binding of ¹⁴C-succinyl con A and ¹²⁵I-con A to almost confluent 3T3 and SV3T3 cells attached to plastic tissue culture wells was measured in PBS at 4° C. Low temperature was chosen to minimise endocytosis of lectin molecules bound to the cell surface¹⁹. Since the binding of succinyl con A and con A was complete after 30-40 min, cells were incubated with various concentrations of lectin for 50 min. Although succinyl con A did not agglutinate cells as efficiently as the native lectin, succinyl con A bound almost as well as con A to the surface of SV3T3 cells (Fig. 1), and in other experiments bound to the surface of 3T3 cells as well as the native lectin.

Binding experiments were also carried out in PBS at 37° C in the presence of 10% calf serum to measure binding under the conditions of the growth experiments described later. Under these conditions succinyl con A bound more efficiently than the native lectin although the maximal number of molecules of either lectin bound under these conditions was slightly reduced: at a concentration of $100 \mu\text{g ml}^{-1}$ succinyl con A, 4.2×10^6 molecules per cell were bound and more than 90% of the available binding sites were saturated.

Competition binding studies were carried out to confirm that succinyl con A bound to the same receptor sites as the native lectin. Succinyl con A could inhibit the binding of at least 60% of the ¹²⁵I-con A molecules which bound to SV3T3 cells (Fig. 2). Succinyl con A did not, however, inhibit binding as efficiently as the native lectin. Taken together the results of the agglutination studies and binding experiments suggest that succinyl con A can be used to cover con A binding sites on SV3T3 and 3T3 cells without inducing cell agglutination.

Growth studies

The effects of succinyl con A on the growth of SV3T3, Py3T3 and 3T3 cells have been observed over a wide range of succinyl con A concentrations and under a variety of different growth conditions. For most experiments the effects of succinyl con A at a concentration of $100 \mu\text{g ml}^{-1}$ were tested since the binding studies showed at this concentration more than 90% of the maximal number of succinyl con A molecules were bound.

3T3 cells and SV3T3 cells were obtained from Dr R. Dulbecco, and Py3T3 cells from Dr W. Eckhart. Cells were maintained in Dulbecco's and Vogt's modification of Eagle's medium supplemented with 10% calf serum, 250 units ml^{-1} penicillin and 50 $\mu\text{g ml}^{-1}$ streptomycin at 37°C in a water-saturated atmosphere at 10% CO_2 and 90% air. No mycoplasma were detected by autoradiography. Cells ($3\text{--}5 \times 10^4$) were seeded in 30 mm Nunc plastic tissue culture dishes in 1 ml of culture medium containing 10% calf serum. The next day (day 0) the medium was replaced with fresh medium (2 ml) containing 10% calf serum and the required concentration of succinyl con A. Cell number in duplicate cultures was determined daily by removing the cells from the dishes with 0.05% trypsin and counting the cells in a Coulter counter. Similar results were obtained if replicate cell counts were made on cells removed from the dish with trypsin containing

Fig. 1 Binding of ^{14}C -succinyl con A (\circ), and ^{125}I -con A (\bullet) to SV3T3 cells. ^{125}I -con A (specific activity 7×10^5 c.p.m. μg^{-1}) was prepared by the method of McConahey and Dixon²⁹ and purified by affinity chromatography on Sephadex. ^{14}C -succinyl con A (specific activity 2.5 or 6×10^5 c.p.m. μg^{-1}) was prepared using ^{14}C -succinic anhydride (New England Nuclear). All lectin solutions were filtered through $0.45 \mu\text{m}$ Millipore filters just before use. Cells were grown to 1×10^5 – 2×10^5 cells per well in 16 mm plastic multi-well tissue culture plates (Linbro, Los Angeles). Cell monolayers were washed twice with PBS (1 ml) and incubated with lectin in 0.3 ml PBS for 50 min at 4°C . After incubation cells were washed five times with PBS (1 ml), removed from the wells by overnight incubation with 10% Triton X-100, and the radioactivity bound to the cells determined. Nonspecific binding to the cells was determined as the residual binding in the presence of 100 mM methyl α -D-mannoside. Nonspecific binding of ^{125}I -con A was less than 10% of the total radioactivity bound in the absence of methyl α -D-mannoside. Nonspecific binding of ^{14}C -succinyl con A was 10–20% of the total radioactivity bound. The results reported are corrected for nonspecific binding of the lectins to the cells. Other control experiments showed that in the absence of cells ^{125}I -con A and ^{14}C -succinyl con A bound to wells which had contained only culture medium at 37°C for 24 h. The bound lectin, which was directly proportional to the concentration of free lectin, was reduced by 100 mM methyl α -D-mannoside. Because it is difficult to estimate the contribution of the lectin binding to the plastic (or serum glycoproteins adsorbed to the plastic) in the presence of cells, we have not made a correction for nonspecific binding to the wells. The maximum contribution of lectin bound to the plastic was less than 10% of the total radioactivity measured for the binding of ^{125}I -con A and between 10–30% of the total radioactivity measured for the binding of ^{14}C -succinyl con A.

Fig. 2 Inhibition of the binding of ^{125}I -con A ($20 \mu\text{g ml}^{-1}$) to SV3T3 cells by succinyl con A (\bullet), and the native lectin (\circ). Competition binding studies were carried out as described for direct binding studies. ^{125}I -con A and competing lectin were added to the cells as a mixture in 0.3 ml PBS. No corrections for nonspecific binding were made.

50 mM methyl α -D-glucoside to prevent possible lectin-induced agglutination of the trypsinised cells.

The growth rate and maximum cell density of SV3T3 cells and 3T3 cells was slightly reduced by succinyl con A (Fig. 3). But SV3T3 cells treated with succinyl con A at a concentration of $100 \mu\text{g ml}^{-1}$ still grew to a high cell density before growth stopped and the cells began to die. 3T3 cells treated with succinyl con A stopped growing at a low density and maintained viability. The effects of

Fig. 3 Effect of succinyl con A ($100 \mu\text{g ml}^{-1}$) on the growth of SV3T3 and 3T3 cells. (\circ) SV3T3; (\bullet) SV3T3 + $100 \mu\text{g ml}^{-1}$ succinyl con A; (\square) 3T3; (\blacksquare) 3T3 + $100 \mu\text{g ml}^{-1}$ succinyl con A.

Fig. 4 Effect of succinyl con A ($100 \mu\text{g ml}^{-1}$) on DNA synthesis in SV3T3 and 3T3 cells. (O) ^3H -thymidine incorporation (c.p.m. per 10^4 cells) of cells grown without succinyl con A; (●) ^3H -thymidine incorporation of cells grown with $100 \mu\text{g ml}^{-1}$ succinyl con A; (□) cell density in the absence of succinyl con A; (■) cell density in the presence of succinyl con A. Cells were grown in 1 ml of culture medium which was not changed during the experiment.

succinyl con A on the growth of both cells could be abolished by 50 mM methyl α -D-mannoside in the culture medium demonstrating that specific binding of succinyl con A to the cells was necessary to produce the effects on growth. Succinyl con A had no detectable effect on either the morphology of individual cells or cell cultures.

In the experiment shown in Fig. 3 the culture medium was unchanged throughout the experiment. In other experiments with SV3T3, Py3T3 and 3T3 cells, medium was either partially or completely replaced daily with fresh medium containing the same concentration of succinyl con A. The results of these experiments were the same as those shown in Fig. 3, except that, as expected, all cells grew to higher cell densities. It is therefore unlikely that the reason succinyl con A has little effect on the growth of SV3T3 cells or 3T3 cells is because it is being rapidly degraded by proteolytic enzymes either of cellular origin or present in the serum. In experiments in which culture medium was replaced daily, SV3T3 cells, and to a lesser extent Py3T3 cells, treated with succinyl con A showed a variable tendency to detach from the dish immediately after the culture medium was changed so that experiments with these cells were sometimes difficult to follow for the desired time.

In growth experiments in which the succinyl con A dose was varied, $200 \mu\text{g ml}^{-1}$ succinyl con A (the highest dose tested) inhibited growth of 3T3 and SV3T3 cells only slightly more than $100 \mu\text{g ml}^{-1}$ succinyl con A. When the degree of growth inhibition was plotted as a function of the succinyl con A concentration a saturation curve was obtained which closely resembled the succinyl con A binding curve (Fig. 1). This provides further evidence that the inhibition of growth results from the binding of succinyl con A which occurs to an extent predicted by the binding assays. In contrast to the effects of trypsinised con A on the growth of transformed and normal cells previously reported¹³, succinyl con A inhibited the growth of normal and transformed cells to the same extent at each concentration tested.

Cell cycle analysis

In some growth experiments the rate of DNA synthesis in cell cultures was estimated in replicate cultures by measuring the incorporation of ^3H -thymidine ($2.5 \mu\text{M}$; 1.0 Ci mmol^{-1}) into trichloroacetic acid-insoluble material during a 2 h period (Fig. 4). Daily determinations were made in triplicate. The rate of cellular DNA synthesis remained relatively constant during the first two days of culture when the cells were growing exponentially. As growth slowed there was a large decline in DNA synthesis in cultures of 3T3 cells and SV3T3 cells whether or not the cells were grown in the presence of succinyl con A.

Although DNA synthesis declined in cultures of both normal and transformed cells, microfluorometric cell cycle analysis^{20,21} revealed a profound difference in their growth pattern (Fig. 5). As 3T3 cells reached their saturation density and ^3H -thymidine incorporation dropped, there was a progressive reduction in the proportion of cells in S phase and an accompanying increase in the proportion of cells in G_1 phase. In contrast, no change in the distribution of SV3T3 cells throughout the cell cycle could be detected as their growth slowed. Succinyl con A had no effect on the cell cycle distribution of either cell type at any stage of growth.

The results from microfluorometric analysis and ^3H -thymidine incorporation are consistent with current knowledge of the growth patterns of SV3T3 cells and 3T3 cells. 3T3 cells stopped growing as serum factors are depleted and arrest in G_1 phase^{5,7}, whereas SV3T3 cells continue to grow and eventually die. The dramatic drop in ^3H -thymidine incorporation as SV3T3 cells reach saturation density represents an extreme example of the lengthening of all stages of the cell cycle as nutrients begin to limit their growth^{8,9}.

Our studies provide no evidence that succinyl con A, which binds to con A binding sites, restores the growth pattern of transformed cells to normal. These results are in conflict with the hypothesis that covering of the con A binding sites on virally transformed cells restores normal growth^{13,22,23}. This hypothesis was based upon the effects of trypsinised con A on the growth of Py3T3 cells. Although we used SV3T3 cells in most of our experiments, in other experiments Py3T3 cells treated with succinyl con A also grew to a high cell density. Thus the inability of succinyl con A to restore normal growth seems to be a general phenomenon.

Several explanations could account for the different effects of succinyl con A and trypsinised con A on cell growth. Because of the heterogeneity of the con A binding sites and the failure to completely inhibit ^{125}I -con A binding with succinyl con A, we cannot formally exclude the possibility that succinyl con A and trypsinised con A bind to different fractions of the total receptor population. It should be stressed, however, that this is an unlikely explanation because although no quantitative studies on

Fig. 5 Cell cycle analysis of SV3T3 and 3T3 cells grown with or without succinyl con A ($100 \mu\text{g ml}^{-1}$). Cells were prepared for flow microfluorometry as described^{20,21}. Cells were removed from the dishes, fixed with formalin and stored at 4°C until the end of the experiment. Cell samples were then stained with acroflavine, resuspended in water and analysed for DNA content using a flow microfluorometer equipped with an argon laser ($\lambda 488 \text{ nm}$)²¹. The vertical bars represent the percentage of the cell population in G_1 , S and G_2+M stages of the cell cycle during exponential growth (day 1 or 2) and as the cells reach saturation density (days 4 and 5). Open bars: untreated cells; hatched bars: cells treated with succinyl-con A. The results are the average values from three experiments ± 1 s.e.

the binding of trypsinised con A to the surface of transformed cells have been reported, Burger and Noonan¹³ observed a graded response of cell growth to different doses of trypsinised con A, $10 \mu\text{g ml}^{-1}$ trypsinised con A significantly reducing the saturation density of Py3T3 cells. Binding experiments (Fig. 1 and ref. 24) show that even the native lectin at a concentration of $10 \mu\text{g ml}^{-1}$ saturates less than 25% of the con A binding sites. No differences in the binding of succinyl con A and con A were observed until a lectin concentration of $50 \mu\text{g ml}^{-1}$ when more than 50% of the con A binding sites were occupied.

Alternatively succinyl con A may bind to the same sites as trypsinised con A but after binding behave differently. For example, succinyl con A, in contrast to the native lectin, neither induces clustering of its own receptors nor inhibits clustering of immunoglobulin receptors on the surface of mouse lymphocytes¹⁷. If this should be the case then succinyl con A will be invaluable in identification of the biologically significant events which occur after the binding of trypsinised con A.

A third possibility is that normal growth control is not restored by treating transformed 3T3 cells with trypsinised con A but that trypsinised con A, like the native lectin²⁵, differentially kills transformed cells. In the original experiments of Burger and Noonan¹³ none of the experimental results unambiguously distinguishes between the possible toxicity of trypsinised con A and its ability to induce transformed cells to arrest in G_1 phase and maintain viability. In particular, our experiments indicate that a decline in thymidine incorporation in cultures of transformed cells is insufficient evidence to justify the assumption that the cells are arresting in G_1 phase.

We conclude because of the lack of effect of succinyl con A on the growth pattern of transformed cells that it is unlikely that the covering of con A binding sites on these cells is alone sufficient to restore normal growth.

We thank G. Elias and M. Williams for technical assistance, J. Kiernan for assistance with microfluorometric analysis, and Dr Robert W. Holley for advice, encouragement, and for providing laboratory facilities. This work was supported in part by grants to Dr R. W. Holley from the National Cancer Institute, The National Science Foundation, and the American Cancer Society. I. S. T. is a recipient of a postdoctoral fellowship from The Jane Coffin Childs Memorial Fund for Medical Research. D. A. letters to nature

Redshift of a galaxy near 4C11.50

NEAR the position of the radio source 4C11.50, Wampler *et al.*¹ have found a pair of QSOs separated by 4.8 arc s, with redshifts of 0.4359 and 1.901, respectively. Hazard *et al.*² have noted the presence of a 19-mag galaxy, 10 arc s west of the brighter, lower redshift QSO (4C11.50a); a plate obtained with the 224-cm telescope at Mauna Kea shows that this 'galaxy' is actually a close group of three galaxies. Several spectrograms have been obtained at 190 and 50 Å mm⁻¹, with the two brighter galaxies aligned along the slit at position angle 33°. There is a continuum break downwards to the blue at about 5,700 Å, and an emission line at 5,344.9 Å; these features can be identified with the long wavelength edge of the H and K lines, and with the [O II] λ3,727 doublet, respectively. Assuming an average wavelength of 3,727.4 Å for the [O II] doublet, the redshift is 0.4340 (not corrected for galactic rotation). The two galaxies on the slit are separated by about 2.5 arc s and are not well resolved on the spectrogram, so it is not certain to which one the redshift refers.

The redshift of 4C11.50a itself, determined from the sharp [O III] λλ4,959, 5,007 lines, is found to be 0.4358, in good agreement with the value of 0.4359 given by Wampler *et al.*¹. The difference in radial velocity between the QSO and the galaxy, in the local rest frame of the QSO, is 376 km s⁻¹. This observation is consistent with a physical association between 4C11.50a and the galaxy, and supports a cosmological interpretation of the redshift of the QSO.

Burbidge³ has pointed out that the sort of galaxy which observers tend to select for this sort of exercise is normally in the magnitude range which will give it a redshift similar to that of the nearby QSO. Although this may be true in a rough sense, there cannot be very much accuracy with this kind of preselection. Even if the dispersion in the magnitude of the galaxies is ignored, these magnitude estimates of faint galaxies from casual inspection of the Palomar Sky Survey prints are unlikely to have accuracies greater than ± 0.5 mag. That introduces an uncertainty of approximately ± 20% in the redshift, or ± 15,000 km s⁻¹ in the relative velocity for redshifts near 0.4. 4C11.50a is the third reported case in which an intrinsically bright (on the cosmological interpretation of the redshift) QSO has a redshift within a few hundred km s⁻¹ of the nearest galaxy visible on the Palomar Sky Survey prints. The other two are PKS2251 + 11 (refs 4 and 5) and 4C37.43 (ref. 6).

Search for optical pulsations from Cen X-3

THE optical system recently identified¹ with the X-ray source Cen X-3 is an obvious candidate for high frequency optical studies because it provides the possibility of observing optical effects related to the 4.842 s X-ray pulsations². Observations of this object were made at Cerro Tololo using an S-20 photomultiplier with no filter and making 1-ms integrations on to magnetic tape. The data were analysed by Fourier techniques similar to those used in the HZ Her study³. No clear harmonic activity emerged, and the average upper limits of the optical pulsations for three sets of data were found to be 0.031%, 0.11%, and 0.14% (Table 1).

Table 1 Time series observations of Cen X-3

Date	Telescope (cm)	Starting UT	Phase*	Length (min)	Upper limit (%)
January 24/25, 1974	152	0528	0.691	50	0.031
February 21/22, 1974	91	0121	0.024	400	0.11
February 22/23, 1974	91	0133	0.508	400	0.14

* See ref. 2.

There is, however, a tantalising peak at exactly the Doppler-shifted frequency of pulsation, at the 1.3 σ level. This appeared for an 8 min interval beginning at 0133 UT (phase = 0.508) on the night of February 22/23, 1974 (Table 1). This 'activity', corresponding to a fluctuation of 0.25%, should be regarded sceptically; it is reported here in recognition of the possibility that this object may, like HZ Her, display optical pulsations only rarely^{3,4}.

The detected optical pulsations in Her X-1 are of the same fractional order of magnitude as the observed upper limit for Cen X-3 reported here. The X-ray flux from Her X-1 (refs 5 and 6) is about 2.9 times fainter than that for Cen X-3 (refs 7 and 8). The corresponding optical flux—corrected for reddening taking $A_v = 0.3$ (ref. 9) and 4.3 (W. Krzeminski, personal communication) respectively—is 76 times fainter. Thus, if the pulsed optical emission in these kinds of objects is excited by the absorption of X rays, than significant optical activity at the present limit of detection would require a conversion efficiency about 26 times greater for Cen X-3 than for Her X-1. Although further observational work would increase the chances of detecting sporadic activity, a significant decrease from the present upper limit is not achievable with available instrumentation.

Dynamic evidence on massive coronas of galaxies

A LONGSTANDING unresolved problem in galactic astronomy is the mass discrepancy observed in clusters of galaxies. The virial mass of the cluster per galaxy and the mass-luminosity ratio are considerably larger than the corresponding quantities for individual galaxies. This discrepancy cannot be a result of expansion or be because of the recent origin of clusters; these ideas contradict our present knowledge of the physical evolution and ages of galaxies¹. Therefore it is necessary to adopt an alternative hypothesis: that the clusters of galaxies are stabilised by hidden matter.

The discovery of the emission of X rays from clusters of galaxies can be explained in terms of hot intracluster gas. The mass of this gas, however, is insufficient to stabilise clusters².

Another possible way of removing the mass discrepancy is to suppose that the masses of individual galaxies have been underestimated. This hypothesis is supported by the fact that there is a very slow decrease in the rotational velocity of spiral galaxies, which indicates the pressure of large amounts of matter in their outer regions³. On the other hand, the discovery of large halos in elliptical galaxies^{4,5} indicate that these also contain previously unseen matter.

There have been several estimates of the mass of galaxies, based on the new observational data mentioned^{6,7}. A critical analysis shows, however, that these estimates are very uncertain.

We here attempt to obtain more exact information on the distribution of mass in the outer regions of galaxies.

Consider a body moving in a circular orbit of radius R , with a velocity V_c , around the centre of the galaxy. If mass distribution is spherical, then

$$M(R) = RV_c^2/G$$

is the mass of the galaxy inside the sphere of radius R , where G is the gravity constant. The same formula can be used for a nonspherical mass distribution, neglecting an error of about 10%.

Spiral galaxies contain neutral hydrogen and HII regions moving in the plane of the galaxy in nearly circular orbits. Observations of these objects permit us to calculate the function $M(R)$ in some galaxies at rather large distances from the centre. We have calculated this for five galaxies of different mass. The results for one galaxy (IC342) are given in Fig. 1.

For all galaxies we have also found the mass distribution $M_s(R)$ of known stellar populations—the bulge, the halo and the disk. We assume that these populations are physically homogeneous, in particular that the mass-luminosity ratio of stars is constant for the whole population. The relevant parameters (luminosity, L ; effective radius R_0 ; mass-luminosity ratio, f ; axial ratio of equidensity ellipsoids, ϵ) for all of the populations, have been determined from combined photometric, spectrophotometric, kinematical and radio observations, using previously described methods^{7,8}.

The resulting mass distribution of known stars, $M_s(R)$, deviates considerably from the mass distribution, $M(R)$, derived from the rotation curve. Rejecting the possibility of large systematic deviations from the circular velocity in the outer regions of galaxies, we conclude that galaxies contain

Fig. 1 The distributions of (a) the inner mass, $M(R)$, and (b) the circular velocity, V_c , in the galaxy IC342. Dots, observed values; dashed lines, model functions for known stellar populations; dotted lines, distributions for the corona; solid lines, total distributions. In Fig. 1b two variants of the total velocity distribution are given to demonstrate its dependence on the central density of the corona.

a previously unrecognised, massive population. It is convenient to call this population a 'corona'. We have estimated the parameters of coronas for the five galaxies (Table 1) adopting, for simplicity, an exponential density law

$$\rho(R) = \rho_c \exp(-R/R_0)$$

with spherical symmetry. (A small axial ratio, ϵ , would result in a large part of the kinetic energy being in the form of rotation, although the results of Ostriker and Peebles do not indicate this⁹.)

The available data permit us to derive the central density of the corona, ρ_c , with great accuracy. The length of the observed rotation curve, however, is insufficient to allow any determination of the mass and extent of the corona.

To determine total masses and dimensions of galactic coronas, more distant test bodies are needed. For this purpose isolated pairs of galaxies can be used, with secondary galaxies serving as test bodies for determining the mass distribution of primary galaxies¹⁰.

In the case of double galaxies we know the radial component of differential velocity, $v_r = \Delta V_r$. The projection factor, $p = V_c^2/v_r^2$, which depends on the orientation of the velocity vector and on the shape of the orbit, remains unknown, but its expected value, $\langle p \rangle$, can be calculated. Therefore, the mass distribution function can be found only statistically:

$$\langle M(R) \rangle = \langle p \rangle \langle Rv_r^2 \rangle / G,$$

where $\langle Rv_r^2 \rangle$ is the corresponding mean value for a sample of pairs of galaxies.

We have collected data on 105 pairs of galaxies with known types, radial velocities and estimates of magnitudes and dimensions^{11,12}. To prevent the sample from contamination by optical pairs, only those pairs with signs of interaction or with a small differential motion, $\Delta V_r/V_r < 0.23$, have been considered. The distances have been determined from the mean recession velocity, V_r , using the Hubble constant, $50 \text{ km s}^{-1} \text{ Mpc}^{-1}$. For some nearby pairs other distance indicators have been used. The pairs have been divided into five equal groups according to the radius, R . The resulting function $\langle M(R) \rangle$ is shown in Fig. 2.

We have also calculated the average mass distribution of known stellar populations, $M_s(R)$, and have determined the distribution of mass in the corona, $M_c(R)$ (Fig. 2). The resulting central density agrees well with our previous estimates from individual galaxies. The use of distant satellites as test bodies enables us to derive masses and effective radii of coronas with a sufficient accuracy. There are enough pairs in our sample to allow an estimation of the masses of coronas separately for primary elliptical galaxies and also for bright and intermediate spiral galaxies. The estimated parameters are given in Table 2. In the case of primary elliptical galaxies the total masses of coronas may be underestimated.

Fig. 2 The distribution of the mean inner mass, $\langle M(R) \rangle$, obtained from 105 pairs of galaxies. Symbols as in Fig. 1.

The mass of galactic coronas exceeds the mass of populations of known stars by one order of magnitude, as do the effective dimensions, by a similar factor. The central density of coronas is surprisingly constant: $\log \rho_c = -24.5 \pm 0.1$ (g cm^{-3}).

The presence of massive coronas in galaxies considerably reduces (if not removes) the virial mass discrepancy in clusters of galaxies. The mass-luminosity ratio rises to $f \approx 100$ for spiral and $f \geq 120$ for elliptical galaxies. With $H = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ this ratio for the Coma cluster is 170 (ref. 1).

According to new estimates the total mass density of matter in galaxies is 20% of the critical cosmological density.

The possible physical nature of galactic coronas will be discussed in a separate article.

We are indebted to I. D. Karachentsev, L. M. Ozernoi, R. A. Sunyaev, and A. D. Chernin, for valuable discussions, and to Mrs U. Rummel for her help in the preparation of data.

Origin of QSO absorption lines

THE origin of the absorption lines in QSOs, with $z_{\text{abs}} \ll z_{\text{em}}$ has remained a puzzle. It has been suggested that they result from intervening matter lying along the line of sight but not associated with the QSO^{1,2}. It has also been suggested that the absorption lines arise 'locally' from matter expelled from the QSO core³⁻⁶. In particular, radiation pressure has been proposed as the driving mechanism³⁻⁵. It has, however, been shown that the final velocities required by the expelled matter ($v_f \sim c$) for z_{abs} to be $\ll z_{\text{em}}$, cannot be attained by radiation pressure⁷. Alternatively, matter could be accelerated to velocities $v_f \sim c$ by free electron scattering in the outer region of the QSO core⁷.

Any model that attempts to explain the formation of QSO absorption lines must explain the highly multiple z_{abs} spectra that are sometimes seen, and the distribution of the multiplicities. At least 10 z_{abs} per QSO are required to explain the spectra of the multiple z_{abs} QSOs PHL957, Ton1530, PKS0237-23 and 4C05.34 (refs 9-12).

The observed redshifts, $z_{\text{abs}} (\ll z_{\text{em}})$, in the local interpretation, correspond to final velocities $v_f \sim 100,000 \text{ km s}^{-1}$ and the absorption line widths correspond to velocity dispersions $\Delta v_f \sim 30 \text{ km s}^{-1}$ (refs 13 and 14). A particularly small Δv_f of $\sim 8 \text{ km s}^{-1}$ has recently been observed¹⁵. The basic problem of the local interpretation is to ascertain how a cloud be accelerated to final velocities $v_f \sim c$ yet have a final velocity dispersion $\Delta v_f/v_f \sim 10^{-4}$.

So far the existence of 'plasmoids', consisting of relativistic particles in a magnetic field, is the only mechanism in the local interpretation that has been suggested⁶ to decrease the relatively large possible macroscopic or bulk motions in QSO clouds (velocity dispersions). In the plasmoid mechanism there are several assumptions⁶. First, that an individual plasmoid typically expands adiabatically from $\sim 5 \times 10^{17} \text{ cm}$ to $\sim 10^4 \text{ pc}$; second, that $\sim 10^4$ plasmoids form a single cloud of dimension $\sim 10^4 \text{ pc}$; third, that inhomogeneities in the magnetic field of the single cloud cause density enhancements such that separate regions are created with different z_{abs} ; and fourth, that the different density enhancements have relativistic velocities with respect to one another, thus explaining the large differences in the observed z_{abs} .

As a possible alternative to that plasmoid mechanism, we show here that certain large relative bulk motions in QSO clouds can be dissipated without the presence of strong magnetic fields and without large adiabatic expansions. The essence of the argument is that a cloud with convergent internal velocities can coalesce inelastically because the internal kinetic energy can be dissipated and radiated away.

It is easy to show this when using the known data of QSO absorption clouds. I assume that the cloud, with convergent internal velocities, extends from a distance R_1 to R_2 from the QSO core, and has a velocity profile that decreases with increasing radius ($v(R_1) > v(R_2)$). An ion at R_1 has a relative velocity, \hat{v} , with respect to the neutral atoms in the cloud, where $0 < \hat{v} < \hat{v}_m$. The velocity, \hat{v}_m , is the maximum dispersion velocity of the cloud ($v(R_1) - v(R_2)$) and is taken to be large ($\hat{v}_m \gg 10^{-4}c$).

The average energy loss for an ion per neutral atom, $\epsilon(\hat{v})$, is approximately inversely proportional to $\hat{E}(\hat{v})$, where $\hat{E}(\hat{v})$ is the relative kinetic energy and \hat{v} is greater than a characteristic velocity, v_0 (ref. 16). Thus, $\hat{E}(\hat{v}) \epsilon(\hat{v}) \simeq \hat{E}(v_0) \epsilon(v_0)$. Because the relative velocity, \hat{v} , for an ion at R_1 varies from 0 to \hat{v}_m , the range of the ion in the cloud is of the order

$$\bar{\rho} \equiv [\rho E(v_0) \hat{v}_m^2 / v_0^2 \epsilon(v_0) / n(R_1)],$$

where f is the fraction of the atoms of the cloud which are neutral, and $n(R_1)$ is the particle density of the cloud. Assuming that the cloud thickness, $R_2 - R_1$ is comparable to R_1 , then

the condition for the dispersion velocity, \hat{v}_m , to be dissipated is

$$\bar{\rho} \ll R_1 \quad (1)$$

The density $n(R_1)$ can be related to the column density of the observed absorption clouds, $N_a \equiv n(R_a)\Delta R_a$, where R_a is the average distance of the absorption clouds from the QSO core, $n(R_a)$ is the particle density of the clouds at R_a , and ΔR_a is the shell thickness in which the observed absorption clouds are found. A high probability exists for finding absorption lines in QSOs with large z . This implies that the observed absorption clouds have a solid angle coverage approaching 4π sr. The mass of the clouds is $M = 4\pi N_a R_a^2$. We assume that $R_1 \ll R_a$. The time to expel the clouds of mass M (now at R_a), through a sphere of radius $R_1 < R_a$, is $< R_a/v_r$. It is also $\geq M/4\pi r^2 v_r R$. The density, $n(R_1)$, must therefore obey the relationship $n(R_1) \geq N_a R_a^2$.

The range, $\bar{\rho}$, in equation (1) thus obeys the relationship $\bar{\rho} < \bar{\rho}_m \equiv E(v_0) \hat{v}_m^2 / v_0^2 \epsilon(v_0) / N_a R_a$. Using existing experimental data we can evaluate $\bar{\rho}_m E(v_0)$ for protons in helium at ≈ 100 keV. The $\epsilon(v)$ for protons in helium has been measured and found to be $\sim 7.0 \times 10^{-15}$ cm² eV at 100 keV, and $\sim 6.5 \times 10^{-15}$ cm² eV at 40 keV (refs 17-20). Helium atoms in the absorption cloud will be the first atoms to recombine, and so $\epsilon(v_0) \approx 7.0 \times 10^{-15}$ cm² eV can be taken for the evaluation of $\bar{\rho}_m$. Burbidge and Chan²¹ evaluated the column densities of the QSOs PHL938, PKS0237-23 and Ton1530. They find that $N_a \approx 10^{19}$ cm⁻², which we assume to be true. Bahcall and Goldsmith¹⁰ placed a lower limit of 10^3 pc on R for the QSO 4C05.34, which we also assume to be true. We then have $\bar{\rho}_m \approx 10^{-4} \hat{v}_m^2 R_a^2 / v_0 f$, where \hat{v}_m and v_0 are in units 10^3 km s⁻¹ and R_1 is in pc.

Reasonable estimates of \hat{v}_m , R_1 and f give $\bar{\rho}_m/f \ll 1$ (for example $\hat{v}_m \sim 10^{-2} c$, $R_1 \sim 1$ pc, $f \sim 0.01$). The condition of equation (1) then seems to be satisfied.

It is of interest to estimate the final equilibrium velocity, \hat{v}_e , that the particles attain in the cloud. At very low energies, an important factor that must be taken into account is that the particles no longer travel in straight lines. Although traverse in a straight line are a good approximation when \hat{E} is large compared to atomic energies ($\sim I$), this assumption is not valid at very low energies (that is, when $\hat{E} \sim I$). When \hat{E} becomes comparable to I , large transfers of momentum can occur. Rather than scattering primarily in the forward direction, as at high energies, the scattering becomes approximately isotropic for $\hat{E} \sim I$. If ΔE is the average energy loss per collision, then the energy, ΔE , will be small, because most collisions at very low energies are elastic. The ratio of the range $\rho(\hat{E})$, of a particle, which occurs when large transfers of momentum are important to the range of the particle travelling in a straight line, $\rho_s(\hat{E})$, is $\rho(\hat{E})/\rho_s(\hat{E}) \sim N^{1/2}$, where $N \sim E/\Delta E$. For example, if $\Delta E \sim 0.1$ eV and $E \sim 100$ eV, then the ratio is $\sim 1/30$.

Particles in the cloud will lose energy at an appreciable rate as long as $\hat{E} > \bar{E}_i$, where \bar{E}_i is the average ionisation energy ($\bar{E}_i < I$). The inelastic cross section will rapidly decrease when $\hat{E} < \bar{E}_i$. Thus, an approximately stable equilibrium velocity occurs when $\hat{E}(\hat{v}_e) \sim \bar{E}_i$. Using $\bar{E}_i \sim 13$ eV gives $\hat{v}_e = (2\bar{E}_i/M)^{1/2} = 10^{-2}$, where M , the average atomic mass, is ~ 1 . It is interesting that this value is approximately equal to the observed dispersion velocity of absorption line clouds, $\Delta v_r (\sim 10^{-4} c)$.

There are thus indications that observed QO absorption clouds may have their origin in clouds with internal velocities which are convergent, even through the initial velocity dispersion, $\hat{v}_m \gg \Delta v_r \approx 10^{-4} c$, where Δv_r is the observed velocity dispersion. It might be argued, however, that clouds with internal velocities which are divergent, and with $\hat{v}_m \gg 10^{-4} c$ are as likely to occur as convergent clouds. Although this is true it should be noted that if such divergent clouds do exist it is very difficult to observe them. Because of the breadth of the absorption lines, the ratio of the magnitude of a given absorption line from such a cloud, to the magnitude of the line from a con-

vergent cloud, is $\ll 1$. For example, if $\hat{v}_m \sim 10^{-2} c$ the ratio is $< 1\%$.

The gas in a convergent cloud will be very highly ionised. In our discussion we have tried to be conservative and we therefore used $f \approx 0.01$, that is, the cloud is 99% ionised. The cloud will be heated further because of, for example, adiabatic compression ion-atom collisions and the formation of shock waves. The mechanism described for the formation of a cloud with a narrow velocity dispersion, requires that the cooling time is shorter than the dynamical scale of time. The question whether the heat can be radiated away before the cloud has time to rebound can only be answered by a detailed analysis of the dynamical equations.

I wish to thank Drs David C. Black, Lawrence J. Caroff and Jeffrey D. Scargle for helpful comments. Part of this work was performed while I was a National Academy of Science-National Research Council Senior Postdoctoral Research Associate.

Absorption of gamma rays in intense X-ray sources

It has been proposed that intense X-ray sources could also be candidates for γ -ray sources, but there has been no experimental evidence. This can mean either that no γ rays are produced or that they are absorbed before they leave the source. Under certain assumptions about the geometry of the X-ray source one can show that the γ rays are strongly absorbed as a result of pair production with the X-ray photons. On the other hand, measurements on hard photons above the X-ray band may allow us to derive information on accretion sources by virtue of their absorption mechanism.

The importance of photon-photon absorption in astrophysics was first mentioned by Nikishov¹. He calculated the

absorption of high energy γ rays (10^{12} eV) on thermal photons in intergalactic space. Jelley² considered the same absorption mechanism within possible γ -ray sources. McBreen³ pointed out that γ rays from the Crab nebula should already be absorbed for γ -ray energies > 50 MeV as a result of pair production with the X-ray photon field. The following calculations describe the absorption of γ rays in some intense X-ray sources using recent data.

Two photons of energy E_x , E_γ can produce an electron-positron pair in a collision provided that

$$E_x E_\gamma \geq 2(mc^2)^2 / (1 - \cos \alpha) \quad (1)$$

where m is the electron mass and α is the angle between the directions of motion of the two photons. For a fixed γ energy E_γ the cross section σ is a function of the X-ray energy E_x (ref 4). The cross section σ rises steeply from a threshold $E_x = E_s$ given by equation (1), it has a maximum value at $E_x = 2E_s$ and falls off as E_x^{-2} for X-ray energies $E_x \gg E_s$.

We describe the absorption of the γ rays by calculating the dimensionless optical depth τ . The γ -ray intensity then varies as $I_\gamma = I_{\gamma 0} \exp(-\tau)$. Detailed calculations of τ assuming an isotropic radiation field are given by Gould and Schröder⁵. For simplicity it can be written

$$\tau = r \int \sigma n_x dE_x \quad (2)$$

taking the cross section σ and n_x , the density of X-ray photons per unit energy, to be constant throughout the source.

Both σ and n_x are functions of the X-ray energy E_x . r is the length along which absorption takes place. Furthermore, we assume that the angle α in equation (1) is 90° . If we approximate σ by a rectangular function with height $\sigma_0 = 1.7 \times 10^{-25}$ cm² and width $2.5E_s$ we get from equation (2)

$$\tau \approx r \cdot \sigma_0 n_x(2E_s) \cdot 2.5E_s \quad (3)$$

where we have chosen n_x at the energy $2E_s$, corresponding to σ_{\max} .

Equation (3) gives τ as a function of the γ -ray energy E_γ because from (1) we have

$$E_s = 2(mc^2)^2 / E_\gamma \quad (4)$$

To estimate n_x we use observational data⁶⁻⁸. If f is the flux of X-ray photons per unit energy measured on Earth we have approximately

$$n_x = f 4\pi R^2 / 4\pi r^2 c \quad (5)$$

where R is the distance to the X-ray source and r the size of the source which we take to be equal to the length where we have absorption.

To get reasonable values for r we refer to current models of X-ray sources. We calculated the optical depth for three different X-ray sources, Her X-1, Cyg X-1 and the Crab pulsar. For Her X-1 we take $r = 10^5$ cm, the size of the magnetic pole region on the surface of an accreting neutron star⁹. For Cyg X-1 we have $r = 10^6$ cm assuming an accretion disk around a black hole as the X-ray source⁹. In the case of the Crab pulsar we take $r = 3 \times 10^7$ cm an upper limit for the γ -ray source if the observed γ pulse has a halfwidth of about 1 ms.

Figure 1 shows τ as a function of the γ -ray energy E_γ .

It can be seen from Fig. 1 that we cannot expect γ rays above 10 MeV depending on the parameters of the source. On the other hand the electron-positron pairs produced by the absorption of the γ rays can be partly stopped and they then annihilate. This 511 keV radiation is no longer absorbed by the X-ray photon field and can probably escape depending on the matter density present.

If there are pulsed γ rays from the Crab above 10 MeV as claimed by some authors, this would not contradict the above result. From equation (1) we see, that the threshold energy E_s goes to infinity in the case of beamed radiation ($\alpha = 0$).

Fig. 1 τ as a function of the γ -ray energy E_γ . a, Her X-1; b, Cyg X-1; c, Crab.

One can speculate whether there exist other sources where the optical depth $\tau(E_\gamma)$ might be less than 1. From equations (3) and (5) we get

$$\tau \propto L_x / r \quad (6)$$

with $L_x = 4\pi R^2 f$. τ can be small for large r and small L_x .

Examples of the first case are Seyfert galaxies. If we take $r = 10^{-25}$ c, $L_x = 10^{42}$ erg s⁻¹ and compare with the corresponding parameters of Her X-1 ($r = 10^5$ cm, $L_x = 10^{37}$ erg s⁻¹) taking from Fig. 1, we obtain a value for τ , in the case of Seyfert galaxies, much less than 1.

An example of the second case could be an optically thin relativistic plasma of say $kT = 10$ MeV becoming thermally unstable. Ninety per cent of the energy would then be radiated within the energy range 1 MeV–10 MeV. Certainly, the temperature of such a plasma cannot exceed 20 MeV because of cooling caused by the production of electron-positron pairs¹¹. If there is not much X radiation compared with the γ radiation this also has some influence on the Eddington limit which sets an upper limit for the mass flow in an accreting object. The corresponding maximum luminosity is proportional to σ^{-1} , the cross section in the interaction between the infalling matter and the outgoing radiation field. Thus, we can have higher luminosities for γ -ray sources than for X-ray sources. This factor could be as large as 150 for γ energies above 20 MeV.

I thank Professor Martin Rees for drawing my attention to this problem. The work was done during a visit to the Institute of Astronomy in Cambridge, England.

Energy source for comet outbursts

A COMET nucleus is generally recognised as an icy conglomerate, as was originally proposed by Whipple¹. The Orbiting Astronomical Observatory observations of Comet Tago-Sato-Kosaka² and Comet Bennett³ support the current ideas that H₂O is a major component of comets. If comets were indeed formed through an accretion mechanism at distances of many AU from the Sun, what is the nature of the resulting form of water ice?

A number of studies on the deposition of water vapour at low pressures and temperatures indicate that amorphous ice is formed. The reported physical properties include: a density of 2.3 g cm⁻³ (ref. 4), a specific heat 25% greater than that of ordinary hexagonal ice, and a latent heat for the phase transition from amorphous to cubic ice of 24 ± 2 calorie g⁻¹ (ref. 5). The transition occurs at a temperature near 140 K (ref. 6). The presence of impurities seems to enhance the growth of clathrate hydrate ices, but both the clathrates and the amorphous water ice can apparently coexist at densities of 1.4–1.7 g cm⁻³ (ref. 4). Clathrate compounds have densities which are typically 0.3–0.5 g cm⁻³ (ref. 7).

Observational evidence indicates that comet outbursts require an internal energy source⁸. If at least the surface of a comet nucleus contains a substantial percentage of amorphous ice, then the phase transition of the amorphous ice to a cubic structure provides a release of energy which may be responsible for the outbursts observed in many comets. In addition, if the density of amorphous ice is indeed about 2 g cm⁻³, then a 'pulverising' mechanism would exist because of the abrupt stresses introduced by the volume change in the solid as the density of the ice changes by a factor of two.

The total energy released during a cometary outburst is of the order of 10²¹ erg with an accompanying mass loss of 10¹² g (ref. 8). The resulting energy requirement of 10⁹ erg g⁻¹ compares favourably with the 10⁹ erg g⁻¹ released during the amorphous–cubic phase change.

Any theory to explain cometary outbursts must consider the spatial distribution of the phenomenon. Figure 1 reports the results of a study in which the positions of the comets are shown at the time of outburst⁹. Although some observational selection effects may be present, a definite clustering is apparent within 2.5 AU from the Sun. Calculations¹⁰ have shown that celestial bodies consisting of water ice with an albedo of 0.6, at a distance of 2.5 AU from the Sun, have expected surface temperatures ranging from 150 K for a rapidly rotating sphere, to 180 K for a non-rotating sphere (see Figs 1 and 2 of ref. 10). The phase transition from amorphous to cubic ice requires a temperature near 140 K. Higher temperatures are necessary if the surface has an insulating layer such as that predicted in the model we shall present here.

Any volume element which undergoes this phase transition increases its temperature by about 45 K. Therefore, the heat released can trigger the surrounding material so that the phase change is, in effect, a self feeding mechanism which propagates to a distance where the local temperature is near 100 K.

The outburst of a comet can therefore be envisaged as occurring in a series of consecutive steps: initiation, propagation, pulverisation, sublimation, ejection, and insulation.

Depending upon the condition of the surface of the comet, the amorphous–cubic ice phase transition can be achieved at different solar distances. If the surface is amorphous ice, an outburst is most probable at about 2.5 AU from the Sun. If the surface is covered with an insulating layer, however, a

closer approach to the Sun is required. On the other hand, if amorphous ice is in heat exchange with material with a temperature which increases faster than that of the ice, then an outburst can be expected at greater distances. If the temperature of the ice is slightly below the transition temperature, thermal spikes provided by solar activity could trigger the outburst.

Once the phase transition has been initiated, it will propagate within a region where the temperature of the ice is greater than 100 K. The volume into which the transition can propagate can be estimated. Our calculations consider a spherical comet with a radius of 5 km. For a rough estimate we assume that the surface temperature around the subsolar point decreases as a cosine function. For a subsolar temperature of 140 K, the surface area with a temperature above 100 K is bounded by a circle and contains 14% of the total surface area of the comet. Following Sommerfeld's¹¹ development, it is possible to estimate the depth at which the phase transition terminates 1 m below the subsolar point. For this calculation the thermal diffusivity of glass, 2×10^{-2} cm² s⁻¹, is used. As this depth is reduced to zero at the perimeter of the previously computed area, an average depth of 50 cm is assumed. The resulting volume which undergoes the phase transition is 2.2×10^{13} cm³. The density of amorphous ice is about 2 g cm⁻³ and so the mass involved is 5×10^{13} g.

The transformation of amorphous ice into cubic ice with a density of 0.94 g cm⁻³, must induce severe strains of the order of 20–30% which will pulverise the ice. It is useful to estimate the particle size which results from the fracturing process. For a stress, S , of about 10⁴ pound inch⁻², W is proportional to S^{-4} , where W is the average mass of the ten largest particles that result when the stressed material fractures. If this relationship holds in general for higher stresses, then an extrapolation to the anticipated stress encountered for the amorphous–cubic ice transformation ($\sim 10^6$ pound inch⁻² for strains of 20–30%), shows that W is of the order of 4×10^{-9} g. This implies that the largest particle has a size of about 10 μ m.

This mechanism therefore automatically provides a source of particulate matter which creates a huge surface area. Consequently, the equilibrium vapour pressure between the particulates will be rapidly established. With the mass (5×10^{13} g)

Fig. 1 Positions of comets at the time of outbursts. ○, Hypothetical outbursts preceding discovery; ●, observed outbursts after discovery⁹. (Courtesy of the IAU.)

involved in the phase transition the energy, E , which is released, is given by:

$$E = 5 \times 10^{13} \text{ g} \times 24 \text{ calorie g}^{-1} \\ = 10^{15} \text{ calorie}$$

This can generate water vapour of mass, M :

$$M = E/H = 10^{15} \text{ calorie}/650 \text{ calorie g}^{-1} \\ = 1.5 \times 10^{12} \text{ g}$$

where H is the heat of sublimation. This means that 3% of the generated particulate matter is sublimated. This gas must certainly expand into the vacuum of space at a few times the velocity of sound, carrying with it, at least to an order of magnitude, a comparable mass of dust. This mass is consistent with observed values for typical comet outbursts⁸.

A large fraction of the fractured material remains on the surface. This effectively creates an insulating layer with a high albedo which tends to prevent further outbursts for some time.

This picture of comet outbursts can be subjected to many refinements, such as variations of comet sizes, or of rotation rates and inclinations, impurities and inhomogeneities in the ice, and orbital parameters. The general features of this theory are, however, consistent with observations and in our opinion provide for a more plausible source of energy than has been previously suggested. Those suggestions have included the vaporisation of pockets of methane and/or carbon dioxide⁸, explosive radical reactions¹², and collisions with interplanetary boulders.

We thank Dr C. L. Hemenway of the Dudley Observatory, New York for discussions and Drs W. T. Brydges and T. R. Kozlowski of the Corning Glass Works, Corning, New York for providing the glass shattering data. We also acknowledge support from NASA.

Ratio of the temperatures of the quiet Sun and the centre of the new moon at $\lambda = 1.3 \text{ mm}$

As radio wave spectral line observations are made at ever shorter wavelengths, the need for precise calibration increases. This is because, as a larger portion of the frequency spectrum becomes available for observation, an increasing number of multiple molecular transitions will be detected. To obtain reliable excitation parameters from these detections they must be calibrated accurately at each frequency. Linsky¹ has proposed the Moon as a radiometric standard for observations of extended sources in the infrared, millimetre and microwave portions of the spectrum. We therefore measured the ratio of the quiet Sun temperature to that of the centre of the new Moon

at 231 GHz ($\lambda = 1.3 \text{ mm}$).

The 36-foot telescope of the National Radio Astronomy Observatory (NRAO) was used for the measurements, on June 30, 1973. At $\lambda = 1.3 \text{ mm}$, using a 1.21λ by 1.77λ feed horn, the telescope has a beam size of 44'' × 51'' of arc as measured on Jupiter. A single ended mixer receiver was used that incorporated a Schottky-barrier diode as the nonlinear element². The noise temperature of the double-sideband receiver was 6,000 K, and the intermediate frequency bandwidth was 60 MHz, giving a ΔT r.m.s. of $\sim 1.5 \text{ K}$ with a time constant of 0.25 s.

At this frequency, antenna calibration is rather uncertain and atmospheric attenuation can be quite high, and so it was decided to carry out the observations when the Sun and Moon were close together in the sky. This allowed a comparison of brightness temperatures without any first order dependence on either the antenna or the atmospheric calibration. June 30, 1973 was the date of a total solar eclipse and during our measurements the centres of the Sun and Moon were separated by 6° 45' in the sky: the elevation of the Sun was 41.7° and that of the Moon was 47.7°.

The absolute temperature scale of the receiver was calibrated by placing absorbers, alternately at room temperature and liquid nitrogen temperature, in front of the feed of the antenna. Sky dipping data gave an average value of $\sim 1.2 \text{ db}$ attenuation/atmosphere (clear weather; 27° C; 35% relative humidity) which implied a differential attenuation of 0.18 db between the central solar and lunar positions. The Sun was observed through the dome of the telescope which had been previously measured (using the Moon) to have an attenuation of 2.87 db.

Antenna temperatures referred to an elevation angle of 41.7°, which, if corrected for dome and differential atmospheric attenuation would be 2,481.5 K and 53.2 K for the centres of the Sun and Moon respectively; a value of 46.6 for their ratio. Assuming that the temperature of the quiet Sun is 5,800 K at $\lambda = 1.3 \text{ mm}$, a value of 124.5 K is derived for the central lunar temperature at new Moon.

An examination of H α and K spectroheliograms of the Sun taken on the day of our observations by the McMath-Hulbert Observatory, showed that except for a small flare close to the eastern limb of the Sun, the solar disk, particularly the central region where our observations were taken, was free from any major disturbance. This was confirmed by drift scans of the Sun during the observations. Thus, we are confident that the ratio quoted does refer to the quiet Sun.

Because of our method of observation, the value we have derived for the ratio of the quiet Sun to that of the new Moon is relatively insensitive to any errors in the absolute calibrations of the atmospheric attenuation, the antenna or the receiver. The value mainly depends on the linearity of the detector and the noise on the signal. Thus, we calculate that the error on the derived ratio—46.6—is ± 0.4 .

Bastin *et al.*³ quote the error on their solar measurement as $\pm 400 \text{ K}$. Consequently, the value we have derived for the central lunar temperature at new Moon—124.5 K—has an uncertainty of $\pm 8.6 \text{ K}$.

We thank Dr T. E. Graedel for obtaining the spectroheliograms. The NRAO is operated by the Associated Universities Inc. under contract with the National Science Foundation.

Oldest and largest lunar basin?

MANY questions in lunar science have not yet been answered satisfactorily.

What, for example, is the origin of the nearside-farside asymmetry of the Moon? Why are Oceanus Procellarum and Mare Imbrium richer in KREEP (basalt rich in trace elements) than any other region on the Moon? Why are the lunar Appenines apparently not composed of anorthositic highland crust? I suggest here a possible solution to these, and other, problems.

The nearside-farside asymmetry is evident from the dark mare material which fills the circular basins on the nearside. Although there are similar basins on the farside, they are apparently not filled with mare basalt. Laser altimeter data suggest that this may be a result of the greater thickness of low density crust on the farside. The surface of the farside is largely elevated from a sphere of radius 1,738 km, centred on the Moon's centre of gravity, and the nearside is correspondingly depressed¹. Although this may explain why Maria occur only on the nearside, the differences in crustal thickness are still unaccounted for. Either the Moon accreted heterogeneously, or else low density crust was, at some early stage of lunar evolution, transferred from the nearside to the farside. A possible mechanism for the transfer of vast quantities of crustal material could involve a very major impact on the nearside.

Measurements with γ -ray spectrometers have revealed that the levels of natural radioactivity (which results from U, Th and K) are considerably higher in Oceanus Procellarum and Mare Imbrium than anywhere else on the lunar surface². These regions are therefore presumed to be richer in KREEP material. It is usually assumed that this distribution of KREEP arose as a result of the Imbrium impact. It has, however, been pointed out that if KREEP was ejected by the Imbrium event then the Haemus Mountains to the east of the Imbrium basin should be as radioactive as the Fra Mauro formation to the south³. This has not been found to be the case.

The age of the Imbrium event is generally taken to be about 3.9 Gyr (refs 4 and 5) whereas the whole rock 'isochron' ages for KREEP rocks are much older⁶, suggesting that KREEP basalts were extruded long before the Imbrium impact. The present day distribution of KREEP may, in fact, largely represent the extent of these original lava flows. The subsequent redistribution by the Imbrium impact may only have been a second order effect.

Before the Apollo 15 mission it had been expected that the lunar Appenines would consist of anorthositic crust, supposedly uplifted by the Imbrium impact. When samples were returned from the Appenine front, however, they were found to have predominantly a KREEP composition, and there were few truly anorthositic rocks. This lack of anorthositic crust in the region has since been confirmed by the results of the X-ray fluorescence experiments. The measured Al:Si ratio from the Appenines is about half the value obtained from the Descartes highlands⁷. These results suggest that the original crust in this region was removed and replaced with KREEP basalts, before the formation of the Imbrium Basin.

I propose that soon after the formation of the lunar crust the Moon collided with a planetesimal which was even larger than the projectile which formed the Imbrium Basin. This collision produced a basin 1,200 km in radius centred at 23°N 29°W (Fig. 1). Its size and position are defined by the highlands to the west of Oceanus Procellarum and to the north of Mare Frigoris, and by the western edge of the Southern Central Highlands. There is no evidence for the presence of any appreciable amount of anorthositic crust within this region. It must therefore have been largely removed, and at least some of it may even have been deposited on the lunar farside, con-

Fig. 1 The location of the 'Gargantuan Basin' on the lunar nearside.

tributing to the observed excess crustal thickness there. It is not unreasonable to suppose that this basin was subsequently filled with KREEP basalt lavas. This volcanic activity probably occurred about 4.3 Gyr ago; a date based on the whole rock 'isochrons' for Apollo 14 and 15 KREEP, and Apollo 16 VHA basalts⁶. Alternatively, the activity may have been as recent as 4.14 Gyr if only the Apollo 14 and 15 results are considered. About 3.9 Gyr ago the Imbrium impact redistributed these basalts, in the form of KREEP rich breccias, to the Fra Mauro formation and elsewhere^{4,5}. At the same time the lunar Appenines, largely composed of KREEP, would have been uplifted (see Fig. 2).

All of the large impact basins on the lunar nearside have circular, positive gravity anomalies, or mascons, associated with them⁸. The existence of the mascons, which are usually attributed to the presence of thick lenses of high density mare basalt, implies hydrostatic disequilibrium and provides a powerful constraint on any model of the thermal evolution of the Moon. The circular basin proposed here, however, does not have an associated mascon. If this basin was indeed filled with KREEP basalt 4.3 Gyr ago, in sufficient quantities to produce a mascon, the lunar crust at this time cannot have been rigid enough to support it. The absence of a mascon corresponding to this 'Gargantuan Basin' thus provides a very strong constraint for lunar thermal models.

If the Gargantuan Basin exists, the collision which produced it could have occurred before lunar capture by the Earth, during lunar capture, or after the Moon was in Earth orbit. One speculative possibility is that the Moon was originally in an eccentric solar orbit, possibly between Mars and Jupiter. Following a collision with a minor planet, that original orbit became perturbed into an orbit which crossed the Earth's, and the Moon was subsequently captured by the Earth. A second possibility is that the planetesimal which formed the basin was a minor terrestrial satellite which collided with the Moon as it passed near the Earth at a high velocity. Collision with a minor Earth satellite is a mechanism which could allow efficient lunar capture⁹. If the impact did indeed result in the capture of the Moon by the Earth, then the other large basins must all have formed when the Moon was in Earth orbit. Either the projectiles which produced them were themselves in

Fig. 2 The evolution of the lunar nearside: *a*, Differentiation of the lunar crust (4.6 Gyr); *b*, formation of the 'Gargantuan Basin', and deposition of excavated crust on the lunar farside; *c*, eruption of KREEP basalts (4.3 Gyr); *d*, deposition of ejecta from major basins (such as Serenitatis, 4.3-3.9 Gyr); *e*, deposition of the Fra Mauro formation (FM) and uplift of lunar Apennines (A) by the Imbrium impact (3.9 Gyr); *f*, eruption of mare basalts (3.8-3.2 Gyr). Earth orbit and were collected as the Moon receded from the Earth because of tidal friction, or they may have constituted a family of asteroids in highly eccentric orbits which crossed the Earth's orbit. The inferred low impact velocity of the Imbrium projectile¹⁰ supports the first possibility. In either case it is difficult to explain why the projectiles were not all finally accreted until at least 400 Myr after lunar capture.

Can Einstein's theory of gravitation be tested beyond the geometrical optics limit?

AN upper limit of a few $\times 10^{-3}$ arc s has been placed¹ on the differential deflection of right and left circularly polarised (r.c.p. and l.c.p., respectively) radiation which passes by the Sun from the quasar 3C273. The separation of quasar images in r.c.p. and l.c.p. radiation permits a measurement of the effect of gravitation on polarised radiation. This seems to be the first experiment in which Einstein's theory of gravitation is tested beyond the geometrical optics approximation. Here, I estimate the new effect (that is, the differential gravitational deflection of polarised radiation), and point out that though, using present techniques, it is too small to be measurable for the Sun, it is, however, potentially observable for gravitationally collapsed objects.

Electromagnetic waves in a gravitational field can be thought of as propagating in flat spacetime but in the presence of a 'medium' with properties which are given by conformally invariant quantities constructed from the metric tensor of the Riemannian spacetime, in Cartesian coordinates (ref. 2). Here, Greek indices run from 0 to 3, and Latin indices from 1 to 3. Gravitational units, in which $G=c=1$, are used throughout. The electromagnetic field tensor is decomposed in a Cartesian frame, $(t=x^0, x_i=x^i)$ $F_{\mu\nu} \rightarrow (E, B)$, $(-g)^{1/2} F^{\mu\nu} \rightarrow (-D, H)$ to obtain the usual Maxwell's equations in a medium, together with the relationships²

$$D_i = \epsilon_{ij} E_j - (G \times H)_i \quad (1)$$

$$B_i = \mu_{ij} H_j + (G \times E)_i \quad (2)$$

where, $\epsilon_{ij} = \mu_{ij} = -(-g)^{1/2} g^{ij} / g_{00}$, and $G_i = -g_{0i} / g_{00}$. If the vectors $F^\pm = E \pm iH$ and $S^\pm = D \pm iB$, $S_i^\pm = \epsilon_{ij} F_j^\pm \pm i(G \times F^\pm)_i$ are introduced, then the equations

$$(1/i) \nabla \times F^\pm = \pm (\partial/\partial t) S^\pm \quad (3)$$

$$\nabla \cdot S^\pm = 0 \quad (4)$$

determine the properties of waves in a gravitational field³. The coordinate transformation, $t' = t + \phi(x)$, induces the gauge transformation, $G'_i = G_i + \partial\phi/\partial x^i$, and $\epsilon'_{ij} = \epsilon_{ij}$, under which F^\pm remains invariant, $F'^\pm(t', x) = F^\pm(t, x)$, a property which will be used later. G and $U_{ij} = \delta_{ij} - \epsilon_{ij}$, can be interpreted as gravitational vector and tensor potentials, respectively.

In the scattering of electromagnetic radiation from a gravitational field (asymptotically flat spacetime with no other electromagnetic fields present) the r.c.p. radiation ($F^- = 0$, polarisation properties determined at infinity) decouples from l.c.p. radiation ($F^+ = 0$) according to equations (3) and (4). The helicity of the photon is thus conserved. Moreover, if the gravitational field is free of matter, and spherically symmetrical, then the scattering amplitude is independent of the photon helicity and the gravitational field does not alter the state of polarisation of the incident wave. For more general fields, such as the Kerr field or the exterior field of a rotating body, the scattering amplitude is dependent upon the helicity. The physical reason for this is easily seen by writing the equation for waves of frequency ω in the exterior field of a slowly rotating body of mass, m , and angular momentum, $J = J\hat{z}$:

$$[(1/i) \nabla - \omega G] \times F^\pm = \mp i \omega N F^\pm \quad (5)$$

where, $F^\pm = f^\pm \exp(-i\omega t)$; $G = 2J \times r / r(r-m/2)^2$; and $N = (1+m/2r)^3 / (1-m/2r)$. The index of refraction, N , causes a general deflection for any wave packet⁴. The photon interacts with the vector potential G ; not only with its gravitational 'charge' (energy) but also with its spin, because a rotating body produces a gravitational 'magnetic' field. Moreover, $r \gg m$, $G \approx 2J \times r / r^3$, which is the vector potential caused by a gravitational 'magnetic moment' $2J$. The spin of the

photon is parallel (or antiparallel) to its momentum, and therefore the path of a photon in the exterior field of a slowly rotating body depends on its helicity. It should be emphasised that in the geometrical optics limit where terms of the form $\lambda |\partial g_{ij} / \partial x_k|$ are neglected, the rays follow

$$(\nabla S)^2 - 2\omega \mathbf{G} \cdot \nabla S = \omega^2 N^2 \quad (6)$$

regardless of their polarisation. Thus, wave packets with different polarisation states are expected to follow separate paths which differ from equation (6) in the first approximation by terms of the order of $\lambda |\partial G_{ij} / \partial x_k|$, or the amount by which the vector potential varies over the wavelength of the radiation.

The path of a wave packet of frequency ω , $\omega m \gg 1$, moving nearly parallel to the y axis in the y - z plane far away from the rotating object, is expected to be influenced by the gravitational field of the object at distances close to D along the z axis, where $\mathbf{G} \approx \eta \times \mathbf{r}$, $\eta = 2J/D^3 \ll 1$ and $N \approx 1 + 2m/r$. The dimensions of the packet are assumed to be very small compared with D . The new effects are connected with the presence of \mathbf{G} , it is therefore of interest to consider the solutions of the wave equation

$$[(1/i)\nabla - \eta^2 \times \mathbf{r}] \times \Phi \pm = \mp i\omega \Phi \pm \quad (7)$$

which, under the gauge transformation $\Psi \pm = \Phi \pm \exp(i\omega \eta x)$, is transformed into

$$[(1/i)\nabla - \omega \mathbf{A}] \times \Psi \pm = \mp i\omega \Psi \pm \quad (8)$$

with $A_x = A_z = 0$, and $A_y = 2\eta x$. Solutions of equation (8) can be found in the form $\Psi \pm = \Psi \pm(x) \exp(iK_y y + iK_z z)$, together with the dispersion relation

$$\omega^2 = (K_z \pm)^2 + 2\eta K_z \pm + 2\eta \omega (2n \pm + 1) \quad (9)$$

where, $n^+ = 0, 1, 2, \dots$. This relationship implies that for r.c.p. and l.c.p. photons in the same state, $\Psi, n^+ = n^-$, and moving in essentially the same directions:

$$K_z^- - K_z^+ = 2\eta \quad (10)$$

Thus, the paths of r.c.p. and l.c.p. photons propagating in a direction other than the direction of rotation, split because of the interaction of the photon helicity with the angular momentum of the body, as is evident from equation (9). If the waves propagate along the direction of rotation of the body then equation (10) amounts to different indices of refraction for r.c.p. and l.c.p. waves, so that the plane of linear polarisation rotates in the same direction as the body, in agreement with the results of Skrotskii⁵. Therefore, the wave packet under discussion is focused differently, depending on its state of polarisation, and the differential deflection angle is given by

$$\delta = \omega^{-1} |K_z^+ - K_z^-| = \gamma \lambda J / D^3 \quad (11)$$

where $\lambda = 2\pi/\omega$ and γ is a numerical factor which is expected to be of the order of unity.

Harwit *et al.*¹ used 8 GHz radio waves which passed by the Sun at a distance of $\sim 7.8 R_\odot$. For the Sun, $\delta_\odot < 10^{-18} \gamma$ arc s, which is too small to be detectable, even with the improved techniques of very long base line interferometry, which are likely in the near future. The effect is, however, potentially observable for collapsed objects, and may provide a means of measuring the angular momentum of the body.

Qnd mantle creep

EXPERIMENTS on model materials show that the acoustic properties of the low velocity zone (LVZ) can arise from the formation of intergranular fluid or melt with no significant reduction in creep strength. Consequently, only very limited bounds on the asthenosphere can be inferred from seismic data.

The effect of partial melting on the acoustic velocity, v , and attenuation, Q^{-1} , of a material is sensitive to the dihedral angle, θ , of the melt in the solid grain boundaries. Relevant data are summarised in Figs 1 and 2. When $\theta = 0$, the melt wets the grain boundaries and a small volume fraction of fluid is sufficient to decrease greatly v and Q^{-1} . There is no theory which accounts for this. In the interpretation of seismic data, however, $\theta = 0$ is the case of greatest interest because the glass formed by quenching samples of partially melted crystalline rock always wets the grain boundaries. The volume fraction of melt required to account for the LVZ is estimated from the data (Figs 1 and 2) to be about 0.01.

In a multicomponent system with a solidus temperature T_s , and liquidus temperature, T_L , partial melting occurs when $T_s < T < T_L$. The presence of a small quantity of fluid at a temperature above T_s means that grain boundaries no longer offer resistance to plastic deformation and that a liquid path is available for diffusion. If deformation because of diffusion through the fluid is not rate-controlling, the creep strength of a partially melted polycrystal in the absence of tensile stress is hardly affected by the fluid. The creep strength reflects the strength of the individual solid grains, and depends on T/T_m , where T_m is the melting temperature of the pure solid. It should, then, be possible to put a material in which T_m/T_s is large, and $\theta = 0$, in a state of partial melting such that the acoustic attenuation and creep strength are both large and the sound velocity is low.

Fig. 1 Ratio of extensional wave velocity in partial melts at the solidus to that in the solid phase as a function of the volume fraction of melt. a, $\theta = 0^\circ$; b, $\theta = 50^\circ$. Materials are: \square , W-Ag (ref. 6); \circ , Cu-Pb (ref. 7); ∇ , inverted Δ , NaCl-H₂O (ref. 8); +, KCl-AgCl (ref. 9); \triangle , Au-Ag (ref. 7).

This hypothesis has been tested with experiments on an Al-2 at % Ga alloy. In this alloy $T_s = 29^\circ\text{C}$ and $\epsilon = 0$; T_m for pure aluminium is 660°C . Above 29°C the alloy attains about 1% melt; it has no tensile strength and can be separated easily into individual grains, each coated by a liquid film. The velocity and attenuation of sound in the Al-Ga alloy have been measured above and below T_s using the method of driven extensional resonance (Table 1). When T_s is exceeded the attenuation increases by a factor of 40 and the velocity drops by 4%. Creep strength measurements have been made on bars of the same alloy loaded in compression at constant stress (Fig. 3). Initially, there is a rapid decrease in strain rate, $\dot{\epsilon}$, identified with transient creep. When steady state creep has been established, after about 10 h at 20°C , $\dot{\epsilon}$ decreases at a constant rate because of the increase in cross section that results from compression. In the experiment illustrated, the temperature was increased from 20 to 33°C after the test had run for 38 h. There was a transient increase in $\dot{\epsilon}$, but after 10 h the creep rate had again become steady and was about the same as that of the alloy containing no melt. Partial melting resulted in no increase in the steady state creep rate.

Table 1 Acoustic properties of Al-Ga alloys

Temperature ($^\circ\text{C}$)	Velocity (km s^{-1})	Attenuation (Q^{-1})
22	5.35	1.0×10^{-4}
32	5.13	39×10^{-4}

If a material is to offer little resistance to steady state creep deformation, then $T \rightarrow T_1$. If T_1 is much less than T_m the small resistance arises because there is enough fluid to disaggregate the solid structure if $T_1 \rightarrow T_m$ the grains of the solid have an intrinsically low creep resistance, regardless of the detailed nature of the operative creep mechanism¹. It is not necessary that $T \rightarrow T_1$ for the acoustic attenuation to be high and the sound velocity anomalously low. These acoustic characteristics can be produced either by heating slightly above T_s when $(T_1 - T_s)/T_1$ is large or, in rock by the presence of

Fig. 2 Internal friction, Q^{-1} and frequency of extensional resonance relative to the room temperature, f/f_0 , for a Cu-8.13 weight % Ag alloy heated through T_s (ref. 7). At T_s there is a discontinuous change in both Q^{-1} and the frequency ratio. The volume fraction of liquid formed is 1.4×10^{-3} .

Fig. 3 Creep rate of an Al-Ga alloy under constant compressive load, initially at 20°C , and after 38 h, at 33°C .

small quantities of intergranular fluid rich in water. (Open cracks can also cause the acoustic characteristics of the LVZ but are unlikely to occur under high hydrostatic pressure.) The existence of a LVZ is not, therefore, evidence for the presence of an asthenosphere. A gradual variation of mantle strength properties with depth, as predicted on the basis of solid state data²⁻⁴, is fully consistent with the seismic structure of the upper mantle.

Seismic data fail to establish bounds for either the temperature or the strength properties of the upper mantle. They can, however, place a bound on the properties of the lower mantle. All polycrystalline solids with acoustic properties which have been tested to high temperature in the laboratory show a rapidly increasing 'background' internal friction as $T \rightarrow T_m$ (ref. 5). This is thought to be a result of the coupled, stress-induced motion of dislocations and solute atoms, but conclusive evidence is lacking. In order for the acoustic attenuation of the lower mantle to be as low as the observed value of 10^{-3} , the temperature must be below that at which significant background internal friction appears. Comparison with laboratory data on the high temperature background internal friction of polycrystalline ceramics indicates that in the lower mantle, $T < (0.5-0.75)T_m$.

Origin of iron ore by diagenetic replacement of calcareous oolite

MANY non-uniformitarian¹ or quantitatively improbable² hypotheses have been offered to explain the origins of extensive sedimentary rocks rich in iron. Ironstones and iron formations³, here termed non-cherty and cherty iron ores, have, however, two consistent characteristics which suggest that their origins were fundamentally similar and involved processes which are still operative at present⁴. The first is the occurrence of mudrocks, or their metamorphosed equivalents, overlying individual ore beds within a few metres, with the ore beds themselves covered by non chemical sedimentary rock and not eroded. The second is the occurrence of oolite texture in unmetamorphosed deposits which are not closely associated with volcanic rock or shales bearing pyroclastic material. The internal structures of well preserved ferriferous ooids closely resemble those of Recent calcareous ooids. Some Recent ferriferous spherules are concentrically layered⁵ but, unlike the ooids in iron ores, they contain clay minerals other than ferrous septechlorite, and occur collectively only as moderately iron-rich sediments, no thicker than a few tens of centimetres. Extensive beds of ferriferous oolite thicker than 1 m have formed repeatedly throughout the history of the Earth, even within the last 5 Myr (ref. 6).

The problem is how can the precipitation from solution of major quantities of iron and silicon, with or without substantial aluminium, phosphorus and manganese, give rise to extensive beds which contain ferrous minerals and shallow water sedimentary structures. A study of the mid-Cainozoic Paz de Rio iron ore of north-eastern Columbia⁴ has resulted in a genetic model which is most clearly illustrated in reference to Upper Pliocene ore under, and adjacent to, the Sea of Azov (Fig. 1).

Fig. 1 Map 20 of Upper Pliocene lithofacies in the former Sea of Azov. Circles, non-ferruginous sand; crosses, ferruginous sand; horizontal dashes, shale; vertical dashes, ferriferous oolite with overlying shale. Interbedding is represented by alternation of symbols.

Like all other non-cherty ores, the Azov deposit is predominantly oolitic, and the average thickness of continuous iron ore is only a few metres, although thicknesses do reach 52 m locally. The most abundant ore mineral is ferrous, septechlorite rich in aluminium (chamosite), which is partially replaced by siderite⁶. Goethitic oolite has formed by the oxidation of chamositic oolite above the present water table in the Kerch Peninsula. Fossil shells and shell molds are common, and barite pseudomorphs of wood are present locally. Soviet investigators have suggested that one

possible origin is the dissolution resulting from bacterial action, of terrigenous sediment on the seafloor, and the precipitation of the derived solutions as chamositic oolite at the sediment-water interface⁷. The concentrations of dissolved aluminium in modern marine water⁷, 0.001 parts per million (p.p.m.), and fluviolacustrine water⁸, < 1 p.p.m., are, however, too low to supply sufficient quantities to an extensive region of hypothetical chamositic sedimentation. There is more aluminium in the Azov ore chamosite⁶ than there is dissolved in all of the oceans of the world. Moreover, the absence of dissolved oxygen, which is required if ferrous iron is to be rendered soluble, is incompatible with transport in very shallow, turbulent water.

I therefore propose that the iron, aluminium, and silicon were dissolved by organic, acid-rich groundwater from the interdistributary clay of a delta which prograded over calcareous oolite deposits. Like calcareous oolite sediment in the modern Caspian and Aral Seas⁹, Upper Pliocene oolite in the Sea of Azov apparently formed far from major river discharge and was circumvented by terrigenous sediment (Fig. 1). Shale covering the oolite is interpreted as representing subsequent deltaic progradation. Rain and flood water trapped between natural levees on the delta would have drained from interdistributary swamps rich in organic material, through the highly permeable oolite, up to distributaries (Fig. 2). Aluminium would have been transported in solution as metallo-organic complexes at concentrations of between one and a few p.p.m., as in some British bogs¹⁰. This has been done experimentally at room temperature in 0.01M humic acid solution of clays¹¹. Organic complexing would have greatly enhanced the solubility of iron, but not that of silicon. The experimentally determined Al:Si molar ratio for solutions of clay minerals in dilute, strongly complexing acids, is close to unity¹¹, similar to the molar ratio in chamosites⁴.

If only free ferric oxide and amorphous aluminosilicates were dissolved under interdistributary swamps, over 20 times (ref. 12) as much deltaic mud as oolite would have been leached before the completion of replacement. Migrating distributaries would have continually eroded weathered silt and clay toward the Black Sea. The duration of replacement may be estimated by assuming a deltaic sedimentation rate of 50 million tons a year (about one-tenth that of the Mississippi River) on to the area of oolite illustrated in Fig. 1, and leaching of a volume of deltaic sediment 30 times greater than that of the oolite replaced. Alternatively, the duration can be estimated using Darcy's Law, by assuming the precipitation of 20 p.p.m. of iron from groundwater, a permeability of 100 darcy for oolitic sediment, and a head loss of 1m between interdistributary swamps and distributary channels (Fig. 2). Both calculations suggest that roughly 10⁵ yr are required for the replacement of 5 m of oolite⁴.

The dissolution of silicates by solutions rich in organic material and the subsequent replacement of calcareous oolite, have been experimentally simulated by Gruner², who found that internal ooid structures were preserved in the ferriferous replacement. The preservation of the internal structure is here attributed to the presence of primary carbonaceous layers within calcareous ooids, which act like templates, as in the replacement of aragonite by calcite¹³. Oxidic ooid layers which alternate with chamositic layers in well preserved, mid-Cainozoic ore in Colombia, formed by the oxidation of selected chamositic layers⁴, probably because of differences in the content of organic matter. The greatest loss of oolitic texture in this ore has occurred at the top, possibly as a result of initial rapid dissolution by descending groundwater⁴.

Those who oppose the idea that ferriferous oolite may have originated by the replacement of calcareous oolite, have noted the common occurrence of unreplaced fossil shells beside ferriferous ooids in Phanerozoic ores. Recent

Fig. 2 Hypothetical cross section of groundwater flow from an interdistributary swamp through oolite to a distributary.

oolids are, however, relatively porous aggregates of minute, aragonitic crystallites¹³ which would react readily. Gruner² found that small, calcareous shells were not replaced by solutions which replaced thin sections of calcareous oolite. Opponents to the idea have also noted the lack of lateral gradation from ferriferous oolite to calcareous oolite. But deltaic sedimentation sufficiently potent to fill a lagoon landward from a shallow bank of calcareous oolite, like that in the Aral Sea⁹, would readily cover the entire surface of an oolite bank and cause uniform replacement.

Chamositic oolite has been forming for at least the past 2×10^9 Myr (ref. 14) and cherty, ferriferous oolite has formed at least as recently as the early Jurassic¹⁵. Lower Proterozoic chamositic iron ore is interpreted as recording organic complexing in groundwater which drained interdistributary swamps. The common association of cherty, iron ores poor in aluminium³, of all ages, with volcanic rock or shale containing pyroclastic material¹⁶ suggests that much of the silica and iron was leached from the overlying pyroclastics. A lesser degree of organic complexing during rapid weathering of pyroclastics would have resulted in the decreased solubility of aluminium, whereas iron would have been relatively soluble in a reducing environment under swamps.

The ratio of iron ore to other sedimentary rock is typically very high in Lower Proterozoic ore-bearing sequences, although the total thicknesses within the Phanerozoic of some shallow water sedimentary sequences which include thin ore beds, are comparable to those of the Lower Proterozoic^{4,17}. The difference in the proportion of iron ore is attributed to a difference in the proportion of non-shelly, calcareous sedimentation within slowly subsiding, shallow, restricted basins like the Sea of Azov. Thick ores are attributed to cyclical transgressions of oolite over exposed areas of pyroclastics and/or deltaic sediments which were largely or entirely eroded by fluvial action and marine transgression. Non-calcareous sedimentation unaccompanied by basin subsidence may have lasted longer than calcareous sedimentation without leaving much record.

Cherty ores display a wide variety of textures and structures. Layers of ferrous septeclorite poor in aluminium (greenalite) in some siliceous oolids from the Lower Proterozoic Gunflint Formation of Ontario, are as fine and regular as aragonitic layers in Recent oolids. Elsewhere, the oolitic texture has been partially destroyed during the diagenetic development of compositionally distinct bands¹⁸. Banding is characteristic of most cherty oolite, even where it is non-ferriferous¹⁹, and must be related to the process of silicification. Laterally similar properties of the primary calcareous sediment may have permitted the planar flow of groundwater from which laterally continuous chert layers precipitated.

I therefore conclude that ferriferous oolite is calcareous oolite that has been covered by deltaic sediment and/or pyroclastics which were exposed to weathering and leached.

Water, rich in solutes, drained laterally through the underlying oolite, replacing aragonitic oolids by chamosite if it was rich in aluminium, or by greenalite and chert if it was poor in aluminium. I predict that oxygen isotopic ratios of chamosite in marine ores will indicate precipitation from fresh water. Extensive ferriferous oolite could readily form within the next 10^9 yr by the diagenetic replacement of calcareous oolite in the north-western portion of the Aral Sea⁹.

I thank F. B. Van Houten and H. D. Holland for encouragement and discussion.

In vitro transcription of three adjacent *E. coli* transfer RNA genes

RECENT evidence suggests that the structural genes of some transfer RNA molecules are clustered in groups of two or three on the *Escherichia coli* chromosome¹⁻⁵. The arrangement of tRNA and spacer sequences for two such tRNA clusters have been described⁶⁻⁸. The pattern of transcription of tRNA genes in clusters is not known although the formation of larger precursors in tRNA biosynthesis has been reported^{9,10}. *In vitro* transcription of tRNA₁^{Tyr} gene carried by $\phi 80\text{psu}^+$ phage DNA by purified RNA polymerase was shown to result in the formation of pre-tRNA^{Tyr} molecules bigger in size than mature tRNA^{Tyr}. In the present communication we describe the transcription of a tRNA gene cluster (tRNA₂^{Gly}(su⁺), tRNA₂^{Tyr}, tRNA₃^{Thr}) carried by the DNA of transducing phage λ h80cI857S-t68dglyTsu⁺tyrTthrT (abbreviated λ h80T) recently isolated by Squires *et al.*⁵. *In vitro* transcription of this phage DNA by purified RNA polymerase is shown to produce pre-tRNA molecules of a molecular size consistent with the model of a polycistronic precursor.

The defective transducing phage λ h80T was prepared according to Squires *et al.*⁵ from a double lysogen of strain BF 266. Separation from the helper phage λ h80cI857S-t68 (λ h80H) was carried out by equilibrium density centrifugation.

E. coli ³²P-tRNA was annealed to λ h80T phage DNA in the presence of increasing amounts of unlabelled *E. coli* tRNA, purified tRNA^{Tyr} or a tRNA preparation devoid of tRNA^{Tyr}.

The hybridisation-competition curves presented in Fig. 1 show that unlabelled *E. coli* tRNA competes efficiently with the *E. coli* (^{32}P) tRNA, reducing its hybridisation almost completely. On the other hand, purified tRNA^{Tyr} and a tRNA preparation lacking tRNA^{Tyr} reduce ^{32}P -tRNA hybridisation by only 32 and 65% respectively. These data are in accord with the tRNA gene content described for the λ h80T phage DNA⁵. Due to the presence of three tRNA genes, tRNA^{Tyr} is expected to compete with only one third of ^{32}P -tRNA hybridisation to the phage DNA whereas a tRNA preparation lacking tRNA^{Tyr} should compete only with the hybridisation of the two other RNA species.

Phage λ h80T DNA was transcribed *in vitro* by DNA-dependent RNA polymerase in the presence or absence of ρ termination factor. In order to follow the transcription of the tRNA genes carried by λ h80T DNA we examined the ability of the *in vitro* synthesised RNA to compete with *E. coli* ^{32}P -tRNA for hybridisation sites on the phage DNA. An annealing experiment was carried out using a constant amount of λ h80T DNA and *E. coli* ^{32}P -tRNA in the presence of increasing amounts of *in vitro* synthesised λ h80T RNA. The results presented in Fig. 2a show that the *in vitro* synthesised λ h80T RNA contains polynucleotide chains homologous to those of *E. coli* tRNA. These results also imply that all three tRNA genes carried by λ h80T DNA were transcribed *in vitro* since the synthesised RNA competes efficiently with more than 90% of the hybridisation of *E. coli* ^{32}P -tRNA to λ h80T DNA. The specific production of tRNA₂^{Tyr} sequences was demonstrated using

Fig. 1 Competition of *E. coli* ^{32}P -tRNA with unlabelled *E. coli* tRNA, tRNA^{Tyr} and tRNA devoid of tRNA^{Tyr} for hybridisation to λ h80T DNA. *E. coli* tRNA and ^{32}P -tRNA were prepared as described previously¹². tRNA^{Tyr} was prepared by fractionation of N-carbobenzoyloxy-(^{14}C)-tyr tRNA on a methylated albumin-silicic acid column¹³. The tRNA lacking tRNA^{Tyr} (containing only 10% of the original tRNA^{Tyr}) was eluted from such a column at low salt concentrations while the N-carbobenzoyloxy-(^{14}C)-tyr tRNA was eluted with 1 to 2 M NaCl. λ h80T DNA was prepared as previously described¹¹. Nitrocellulose filters containing 3.5 μg of denatured λ h80T DNA were immersed in hybridisation mixtures of 0.3 ml $2\times\text{SSC}$ (0.3 M NaCl, 0.03 M Na citrate) containing 1 μg of *E. coli* ^{32}P -tRNA (1.2×10^6 c.p.m. μg^{-1}) and increasing amounts of unlabelled *E. coli* tRNA (O—O), tRNA devoid of tRNA^{Tyr} (Δ — Δ) and tRNA^{Tyr} (●—●). After 18 h at 67° C the filters were removed, washed with $2\times\text{SSC}$, treated with pancreatic RNase (25 $\mu\text{g ml}^{-1}$ in $2\times\text{SSC}$), washed again and counted. The radioactivity remaining on the filters was expressed as percentage of control which contained no competing RNA.

Fig. 2 a, Competition between *in vitro* synthesised λ h80T RNA and *E. coli* ^{32}P -tRNA for hybridisation with λ h80T DNA. λ h80T DNA was transcribed *in vitro* by *E. coli* RNA polymerase in the presence of ρ factor. DNA-dependent RNA polymerase was prepared from *E. coli* MRE-600 cells¹⁴ and further purified by low salt glycerol gradient centrifugation¹⁵. Termination factor ρ was prepared from *E. coli* MRE-600 cells as described by Roberts¹⁶. Transcription was carried out in a reaction mixture containing in 10 ml: 50 μmol Tris HCl (pH 7.9); 10 μmol MgCl₂; 1 μmol dithiothreitol; 75 μmol KCl; 0.4 μmol each of ATP, GTP, UTP and ^3H -CTP (4×10^5 c.p.m. nmol⁻¹); 300 μg of λ h80T DNA; 760 units RNA polymerase (2,300 U mg⁻¹) and 65 μg ρ factor. The synthesis was initiated, after 5 min pre-incubation at 38° C, by the addition of the nucleoside triphosphates. The reaction was stopped and RNA isolated as described elsewhere¹¹. The hybridisation mixture contained, in a volume of 0.5 ml $2\times\text{SSC}$, 10 μg denatured λ h80T DNA, 0.9 μg ^{32}P -tRNA (8.5×10^5 c.p.m. μg^{-1}) and increasing amounts of *in vitro* λ h80T RNA. The mixtures were incubated for 90 min at 70° C, loaded on filters and processed as described in legend to Fig. 1. The radioactivity remaining on the filters was expressed as percentage of control which contained no competing RNA. b, Competition between *in vitro* synthesised λ h80T RNA and *E. coli* ^{32}P -tRNA for hybridisation with $\phi 80\text{psu}_L^+$ L strand DNA. λ h80T DNA was synthesised *in vitro* by transcribing λ h80T DNA with RNA polymerase holoenzyme (O—O) or holoenzyme + ρ factor (●—●). $\phi 80\text{psu}_L^+$ DNA preparation and strand separation were as previously described¹¹. The hybridisation mixture contained in 0.3 ml $2\times\text{SSC}$, 2 μg $\phi 80\text{psu}_L^+$ L strand DNA, 0.9 μg ^{32}P -tRNA and increasing amounts of *in vitro* synthesised λ h80T RNA. The mixtures were incubated for 90 min at 70° C, loaded on filters and processed as described above.

the $\phi 80\text{psu}_L^+$ DNA. This transducing phage DNA carries on the L strand the tRNA₁^{Tyr} gene^{11,17} which differs in sequence from tRNA₂^{Tyr} gene by only two nucleotides¹⁸. The difference in sequence between tRNA₁^{Tyr} and tRNA₂^{Tyr} being very small, we assumed tRNA₂^{Tyr} to hybridise equally well to the tRNA₁^{Tyr} gene carried by $\phi 80\text{psu}_L^+$ DNA. Accordingly, we followed the *in vitro* synthesis of tRNA₂^{Tyr} on λ h80T DNA by its competition with *E. coli* ^{32}P -tRNA hybridisation to the L strand of $\phi 80\text{psu}_L^+$ DNA Fig. 2b. These results establish the presence of tRNA₂^{Tyr} chains among the tRNA-like polynucleotides synthesised *in vitro* on λ h80T DNA.

λ h80T RNA transcribed *in vitro* in the presence or absence of ρ factor was fractionated by centrifugation through a sucrose gradient. Figure 3 shows that the total RNA synthesised *in vitro* has a wide size distribution and that transcription of λ h80T DNA in the presence of ρ results in size reduction of RNA molecules having sedimentation constants of 16S or higher. The presence of tRNA₂^{Tyr}-like molecules along the gradient was determined, as described in Fig. 2b, by competition with *E. coli* ^{32}P -tRNA hybridisation to the L strand of $\phi 80\text{psu}_L^+$ DNA. The histograms presented in Fig. 3 show the distribution of the tyrosine specific tRNA-like chains in the gradient fractions. The tRNA₂^{Tyr}-like chains seem to be located in two main fractions (2 and 3) on the gradient and to possess sedimentation values higher than 4S. Once again it is observed that

the presence of ρ during transcription results in a specific increase in the relative amounts of tRNA^{Tyr}-like material possibly by causing termination outside the tRNA genes. Though the presence of ρ considerably reduced the size of λ h80T RNA it seems to have only a minimal effect on the size of tRNA-like material. The distribution of the total tRNA-like material transcribed on λ h80T DNA (tRNA^{Gly}, tRNA^{Tyr} and tRNA^{Thr}) in the gradient fractions was determined as described in Fig. 2a by competition with the hybridisation of *E. coli* ³²P-tRNA to λ h80T DNA and was found to be similar to that observed for tRNA^{Tyr} chains (data not shown). In order to determine more accurately the size of the *in vitro* transcribed tRNA molecules we have analysed fractions 2 and 3 from the sucrose gradient by polyacrylamide gel electrophoresis in the presence of molecular size markers (Fig. 4). From the distribution of the radioactivity of RNA in the polyacrylamide gel, average molecular weights of 2.3×10^5 and 1.2×10^5 are observed for sucrose gradient fractions 2 and 3 respectively.

Are the three tRNA genes of λ h80T DNA part of a single transcriptional unit? Evidence bearing on this question may be obtained by considering the transcription of the tRNA₂^{Tyr} gene. This gene was shown, by electron microscopy studies by Wu *et al.*⁸, to be located between tRNA₂^{Gly} (su⁺₃₆) and tRNA₃^{Thr} genes at a distance of 140 and 260 nucleotides respectively. If the tRNA₂^{Tyr} gene is transcribed in a continuous sequence together with the adjacent tRNAs and spacer regions, the transcript should possess a much higher molecular weight than that of a mature tRNA. The purified RNA polymerase and factors used in *in vitro* studies is a suitable system for the detection of such primary transcription products since it lacks the precursor tRNA processing and modifying enzymes.

Fig. 3 Sucrose density gradient analysis of *in vitro* synthesised λ h80T RNA. λ h80T DNA (250 μ g) was transcribed *in vitro* by RNA polymerase holoenzyme in the presence (●—●) and absence (○—○) of ρ factor in reaction mixtures as described in legend to Fig. 2a. Each preparation of synthesised RNA was dissolved in 150 μ l of $1 \times$ SSC, layered onto a 5 ml of 5–20% sucrose gradient in $1 \times$ SSC and centrifuged for 4½ h at 50,000 r.p.m. and 4°C in SW 50.1 rotor Spinco model L centrifuge. Fractions of 7 drops were collected, aliquots of 1 μ l were precipitated with trichloroacetic acid, filtered through nitrocellulose filters and the radioactivity retained on the filters determined. In the same run, in a separate sucrose gradient, 23S, 16S, and 4S *E. coli* RNA were used as sedimentation constant markers. The histograms (ordinate at right) represent the tRNA₂^{Tyr} content of pooled fractions of RNA synthesised in the presence (|||||) and in the absence (□□□) of ρ factor. The tRNA₂^{Tyr} content was determined by competition with ³²P-tRNA hybridisation on ϕ 80psu⁺ L strand DNA as described in the legend for Fig. 2b. The relative amounts of tRNA^{Tyr}-like material are presented as the reciprocal of the *in vitro* synthesised RNA quantities which reduce by 50% the ³²P-tRNA hybridisation to ϕ 80psu⁺ L strand DNA.

Fig. 4 Evaluation of the size of *in vitro* synthesised tRNA-like material by polyacrylamide gel electrophoresis. Fractions 2 (●—●) and 3 (○—○) of the λ h80T RNA synthesised *in vitro* by RNA polymerase in the presence of ρ factor (Fig. 3) were concentrated to 60 μ l and layered on to a 2% acrylamide, 0.5% agarose composite gel in Tris-EDTA-borate buffer (pH 8.3)¹⁹. 23S and 16S *E. coli* rRNA, 9S rabbit globin mRNA, 5S rRNA and 4S tRNA were used as markers. The electrophoresis was run for 2 h at 0°C and 350 V. At the end of the run the markers were located by staining the gel with 'Stains all' (Eastman Kodak) and the distribution of the ³H-RNA determined by counting 1 mm slices dissolved in 0.3 ml NCS-tissue solubiliser and 3 ml toluene scintillator solution.

The tRNA₂^{Tyr} sequences transcribed *in vitro* were found mainly in RNA molecules with an average molecular weight of 230,000, a value close to that expected for a transcript of three tRNA genes of 80 nucleotides each and spacer regions of 140 and 260 nucleotides. Our findings thus favour the hypothesis of a polycistronic precursor⁵.

We thank Dr J. Carbon for providing us with the λ h80T phage, Dr S. Sarid for help with phage growth and Y. Tichauer for technical assistance.

Uptake of *Escherichia coli* DNA into HeLa cells enhanced by amphotericin B

MAMMALIAN cells in culture take up small amounts of DNA, presumably by pinocytosis^{1,2}. Unlike bacterial cells the mammalian cells do not seem to require a special state of competence for DNA uptake³; and since naked DNA of oncogenic viruses can successfully infect or transform cells⁴, at least some of the DNA taken up by the cells can be functional. In spite of these successful experiments, however, almost all attempts to achieve controlled DNA transformation in mammalian cells have failed. The failure has been attributed to two factors: (1) insufficient transport of added DNA by the pinocytic mechanism¹; and (2) degradation of the foreign DNA in lysosomes⁵.

Modifications of the input DNA by % irradiation or shear⁶⁻¹³ or partial degradation by nucleases¹⁴ have generally only reduced uptake. A few complex polycations, including DEAE-dextran¹⁵, protamine sulphate¹⁶, polylysine and polyornithine¹⁷, do enhance transport into cultured human cells. The enhancement is however at the most two to three-fold. Also the treatments and effects of these agents are difficult to reverse or control, and some of the agents form insoluble complexes with DNA^{18,19} that may not be easily assimilated by cells.

Encouraged by its capacity to promote uptake of a variety of antibiotics into fungal²⁰ and animal²¹ cells, we have tested the polyene macrolide antibiotic amphotericin B (AmB) as a potential agent to enhance uptake of DNA into HeLa cells. Here we report that while the levels of AmB required are high, the transport of DNA is increased 8 to 10-fold under optimal conditions without affecting subsequent cell viability or growth. The process is reversible and can be controlled, because the increased transport stops when the cells are washed free of AmB. Furthermore, the DNA taken up in the presence of AmB is less altered than that transported in its absence.

Figure 1 shows the kinetics of transport of *E. coli* DNA into HeLa cells in culture in the presence of different concentrations of AmB. Acid-precipitable radioactivity was measured in cells after they were washed with medium containing sodium iodoacetate to remove any nonspecifically bound DNA²². Samples incubated without AmB showed the low level of transport already reported²³, whereas samples that contained more than 20 $\mu\text{g ml}^{-1}$ of AmB showed a considerable enhancement in the transport of DNA. The transport was linear for 30 min, and reached a plateau value at 30 to 60 min. In some experiments, further incubation caused a loss of 10%-30% of the net internalised DNA, an observation similar to some earlier reports^{23,24}. After 3 h of incubation at the concentrations of AmB shown, 85-90% of the cells were still viable, as judged by trypan blue dye exclusion. Washed free of DNA and AmB, the

cells uniformly resumed growth and 24 h later had grown as well as untreated cells.

The interdependence of cell number, DNA concentration, and AmB concentration in determining the level of DNA uptake observed is comparable with that observed in the potentiation of antibiotic uptake into fungal cells by AmB (E. Battaner and B. V. K., unpublished work). Figure 2 shows this interdependence, where the ratio of drug to cell number is shown to be particularly important. This

Fig. 1 Kinetics of transport of DNA by HeLa cells. Cells grown in spinner culture in Joklick modified Eagle's medium supplemented with 5% horse serum were centrifuged and suspended in the same medium, but with 10% calf serum. The dispersed cells were counted in a haemocytometer, and then dispensed in 4.5 ml portions into flasks at 37° C with different concentrations of amphotericin B and 77 μg of *E. coli* ³H-DNA. The *E. coli* DNA was prepared by labelling a culture of strain 15T⁻, a thymine auxotroph with ³H-thymine for several generations. DNA was extracted according to ref. 28. It had a specific activity of 12,000 c.p.m. μg^{-1} and showed a characteristic narrow sedimentation distribution in a sucrose gradient at 20° C. At specified time intervals portions of cell suspension were centrifuged and washed twice in incubation medium containing 0.025 M sodium iodoacetate in the cold at pH 7.3 (ref. 22). Each equivalent of 0.5 ml of cell suspension was precipitated with 5% CCl_3COOH . The precipitate was collected on a glass fibre filter and counted in a toluene-based scintillant in a Packard Spectrometer. Acid precipitable radioactivity was plotted per ml of cell suspension. Amphotericin B concentrations used were 200 (○), 100 (○) and 20 (□) μg per ml of cell suspension.

is probably because of the large number of sterol binding sites for AmB per cell²⁵. For example, in the conditions of Fig. 1 with 2.3×10^5 cells ml^{-1} , there was 3.3 times more DNA uptake in the presence of 200 $\mu\text{g ml}^{-1}$ AmB. In optimal conditions with 4.5×10^5 cells ml^{-1} as in Fig. 2, there was 8 to 10 times more DNA uptake.

Transport was inhibited 85-90% by 10 mM sodium cyanide (Fig. 2) which is consistent with the idea that

Fig. 2 Transport of DNA by HeLa cells. HeLa cells (4.5×10^5 cell ml^{-1}) were resuspended as in Fig. 1 and incubated in 0.5 ml portions at 37°C with specified concentrations of amphotericin B and *E. coli* ^3H -DNA. After 30 min, cells were washed and acid-precipitable radioactivity was measured as in Fig. 1. The response to AmB and DNA concentration is indicated. 4.5×10^5 cells ml^{-1} incubated with 2 (○), 4 (□), 8 (△) and 20 (○) μg of ^3H -DNA for 30 min at 37°C at the indicated concentrations of amphotericin B. A second set of samples incubated under identical conditions contained 10 mM sodium cyanide with 2 (●), 4 (■), 8 (▲) and 20 (●) μg of ^3H -DNA ml^{-1} .

uptake might depend on an active process such as pinocytosis²⁶. Also, uptake was temperature dependent: at 0°C , it was completely inhibited in the absence of AmB, and was inhibited 50–60% in its presence.

The effect of AmB on DNA uptake seems to require its simultaneous presence in the medium. For example, when cells were pretreated with AmB (Fig. 3) and washed free of AmB before incubation with DNA, they took up DNA only to the same extent as cells that had not been treated with AmB. This suggests that the binding of the drug to the cell membrane is reversible or temporary in its effect, and confirms that the short time of exposure of the cells to high concentrations of AmB is nontoxic and reversible.

When HeLa cells were incubated with different concentrations of AmB and *E. coli* DNA for 30 min at 37°C , then washed free of AmB and DNA and incubated further in fresh medium, it was found that the acid-precipitable radioactivity in the cells declined steadily. After 8 h only about two thirds of the DNA taken up in untreated cells, and one-third of that transported in presence of AmB was still recoverable from cells. But the DNA extracted from the AmB treated cultures at any one time was relatively more intact, as judged by the sedimentation behaviour of the two DNA samples on an alkaline sucrose density gradient (data not shown).

The possibility that bacterial DNA might be preserved intact longer in AmB treated cells was further supported by DNA-DNA hybridisation trials (Fig. 4). Labelled DNA re-extracted from cells treated with $200 \mu\text{g}$ of AmB ml^{-1} for 30 min reannealed to an extent indistinguishable from the input bacterial DNA; at this time, 70% of the label in cell incubated without AmB hybridised much more slowly. Very probably, it had already been degraded and the products reincorporated at random into HeLa cell sequences.

The apparently prolonged intact survival of DNA sequences taken up in the presence of AmB could increase the probability of it functioning in the recipient cell. The binding of AmB to membrane sterols may increase endocytosis in a way that avoids a direct route to lysosomal vacuoles; or alternatively, the number of new phagosomes simply saturate the lysosomal complement of the cell for some time. At any rate, the advantage of increased survival of intact DNA, combined with the increased levels of uptake and the easy reversibility of the AmB effect, makes AmB a promising agent for permeability control.

Though it is true that our arguments for the incorporation of the DNA into the cells are indirect, two kinds of data support the inference that AmB truly promotes uptake rather than a loose ionic association of DNA with the cell membrane. First, these concentrations of AmB potentiate uptake of a variety of antibiotics^{20,21,27} and of macromolecules that include RNase, DNase and even latex beads $1.1 \mu\text{m}$ in diameter (to be published). Second, the results satisfy the criteria for uptake in previous studies with DNA, including the requirement for energy and the resistance to extensive washing with iodoacetate. We are now testing

Fig. 3 Effect of pretreatment of cells with amphotericin B on the uptake of DNA. HeLa cells (5.0×10^5 cells ml^{-1}) were washed as in Fig. 1 with medium containing sodium iodoacetate and incubated at 37°C for 30 min in 0.5 ml fractions with specified concentrations of amphotericin B. After incubation, cells were washed free of amphotericin B and resuspended in the same volume with $4.4 \mu\text{g}$ of ^3H -DNA (specific activity $24,500$ c.p.m. μg^{-1}). Incubation was then resumed in the presence (●) or absence (○) of amphotericin B at the indicated levels. Cells were then washed and assayed for incorporated DNA as in Fig. 1.

- ARNOLD, V. I. *Ordinary Differential Equations*. Translated and edited by Richard A. Silverman. Pp.viii+280. ISBN-0-262-01037-2. (Cambridge Mass. and London: The MIT Press, 1973.) £16.50.
- BLAKELEY, B. H. *Data Processing*. (The School Mathematics Project—Computing in Mathematics.) Pp.x+68. ISBN-0-521-20198-5. (London: Cambridge University Press, 1973.) £1.20 net.
- DICKEY, R. W. (edited by). *Nonlinear Elasticity*. (Proceedings of a Symposium conducted by the Mathematics Research Center, The University of Wisconsin-Madison, April 16-18, 1973.) Pp.ix+404. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £12.50; £6.
- HENGARTNER, W., and THEODORESCU, R. *Concentration Functions*. (Probability and Mathematical Statistics: a Series of Monographs and Textbooks.) Pp.xii+139. ISBN-0-12-341050-9. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £12; £5.75.
- KRISHNAIAH, P. R. (edited by). *Multivariate Analysis-III*. (Proceedings of the Third International Symposium on Multivariate Analysis held at Wright State University, Dayton, Ohio, June 19-24, 1972.) Pp.xvii+410. ISBN-0-12-426653-3. (New York and London: Academic Press, a Subsidiary of Harcourt, Brace Jovanovich, Publishers, 1973.) £36; £17.30.
- KUJALA, Robert O., and VITTER, III, Albert L. (edited by). *Value-Distribution Theory. Part B: Deficit and Bezout Estimates*. By Wilhelm Stoll. (Pure and Applied Mathematics: a Series of Monographs and Textbooks.) Pp.xi+271. ISBN-0-8247-6125-1. (New York: Marcel Dekker, Inc., 1973.) £15.50.
- MOHLER, Ronald R. *Bilinear Control Processes, with Applications to Engineering, Ecology and Medicine*. (Mathematics in Science and Engineering: a Series of Monographs and Textbooks, Vol. 106.) Pp.xi+224. ISBN-0-12-504140-3. (New York and London: Academic Press, a Subsidiary of Harcourt, Brace Jovanovich, Publishers, 1973.) £17.50; £6.40.
- OSTROWSKI, A. M. *Solution of Equations in Euclidean and Banach Spaces*. Third edition of "Solution of Equations and Systems of Equations". (Pure and Applied Mathematics: a Series of Monographs and Textbooks.) Pp.xix+412. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £34; £16.30.
- PEIXOTO, M. M. (edited by). *Dynamical Systems*. (Proceedings of a Symposium held at the University of Bahia, Salvador, Brasil, July 26-August 14, 1971.) Pp.xiv+745. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £39.
- PHILLIPS, G. M., and TAYLOR, P. J. *Theory and Applications of Numerical Analysis*. Pp.x+380. ISBN-0-12-553556-2. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) n.p.
- RYDE, Folke. *Aspects of the Greatest Integer Function. Part 1: The Greatest Integer Function in the Domain of the Rational Numbers*. P.109. (Stockholm: Almqvist and Wiksell, 1973.) Sw.kr.70.
- WANG, C. C., and TRUESDELL, C. *Introduction to Rational Elasticity*. (Monographs and Textbooks on Mechanics of Solids and Fluids.) Pp.xii+556. ISBN-90-01-93710-1. (Leyden: Noordhoff International Publishing, 1973.) Dfl.130.
- WRIGHTON, R. F. *Elementary Principles of Probability and Information*. Pp.viii+91. ISBN-0-12-765550-6. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £1.95; £5.50.
- ZARISKI, Oscar. *Collected Papers. Vol. 2: Holomorphic Functions and Linear Systems*. Pp.xiii+505. ISBN-0-262-01038-0. (Cambridge, Mass. and London: The MIT Press, 1973.) £17.95.

Astronomy

- BRAY, R. J., and LOUGHHEAD, R. E. *The Solar Chromosphere*. (The International Astrophysics Series.) Pp.xviii+384. ISBN-0-412-10730-9. (London: Chapman and Hall; New York: Halsted Press, a Division of John Wiley and Sons, Inc., 1974.) £9 net.
- GOLDSMITH, Donald, and LEVY, Donald. *From the Black Hole to the Infinite Universe*. Pp.330. ISBN-0-8162-3323-3. (San Francisco and London: Holden-Day, Inc., 1974.) \$6.95.
- STECKER, Floyd W., and TROMBKA, Jacob I. (edited by). *Gamma-Ray Astrophysics*. (A symposium held at NASA Goddard Space Flight Center, April 30 to May 2, 1973, sponsored by the National Aeronautics and Space Administration and the American Physical Society.) Pp.xvi+412. (Washington, DC: Scientific and Technical Information Office, National Aeronautics and Space Administration, 1973. For sale by US Government Printing Office.) \$2.90.

Physics

- BAGGULEY, D. M. S. *Electromagnetism and Linear Circuits*. (The Modern University Physics Series.) Pp.xii+513. ISBN-0-442-00492-3. (London and New York: Van Nostrand Reinhold Company, 1973.) £12 cloth; £5.25 paper.
- BANKS, P. M., and KOCKARTS, G. *Aeronomy. Part A*. Pp.xiii+430. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £28.
- BATES, D. R., and ESTERMANN, Immanuel (edited by). *Advances in Atomic and Molecular Physics*, Vol. 9. Pp.xi+384. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £32; £15.35.
- BERGMANN-SCHAEFER. *Lehrbuch der Experimentalphysik, zum Gebrauch bei Akademischen Vorlesungen und zum Selbststudium. Band III: Optik*. Herausgegeben von H. GOBRECHT. Pp.x+998. ISBN-3-11-004366-1. (Berlin and New York: Walter de Gruyter, 1974.) DM98.
- BUBE, Richard H. *Electronic Properties of Crystalline Solids: an Introduction to Fundamentals*. Pp.xiii+524. ISBN-0-12-138550-7. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1974.) £35; £16.80.
- DAS, Tara Prasad. *Relativistic Quantum Mechanics of Electrons*. Pp.viii+279. ISBN-0-06-041498-7. (New York and London: Harper and Row, Publishers, 1973.) £10.95.
- De BOER, J., and MANG, H. J. (edited by). *Proceedings of the International Conference on Nuclear Physics*, Munich, August 27-September 1, 1973. Vol. 1: Contributed Papers. Pp.lxx+739. Vol. 2: Invited Papers. Pp.xii+837. ISBN-0-7204-0257-3. (Amsterdam and London: North-Holland Publishing Company; New York: American Elsevier Publishing Company, Inc., 1973.) n.p.

EHRENREICH, Henry, SEITZ, Frederick, and TURNBULL, David (edited by). *Solid State Physics: Advances in Research and Applications*, Vol. 28. Pp.xiv+430. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £27.50.

FEDOSEEV, V. A. (edited by). *Advances in Aerosol Physics*, No. 4. Pp.vi+148. ISBN-0-7065-1272-3. (New York and Toronto: John Wiley and Sons; Jerusalem: Israel Program for Scientific Translations, 1973.) n.p.

HASS, Georg, FRANCOMBE, Maurice H., and HOFFMAN, Richard W. (edited by). *Physics of Thin Films: Advances in Research and Development*, Vol. 7. Pp.xiv+421. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £31; £14.90.

HOUSTON, W. V., and PHILLIPS, G. C. *Principles of Quantum Mechanics: The Non-Relativistic Theory with some Illustrative Applications*. Pp.xi+376. ISBN-0-7204-0215-8. (Amsterdam: North-Holland Publishing Company, 1973.) Dfl.110; \$44.

ISRAEL, H., in collaboration with DOLEZALEK, H. *Atmospheric Electricity*. Vol. 2: Fields, Charges, Currents. Authorized and revised translation from the second German edition. (Problems of Cosmic Physics, Vol. 29.) Pp.318-796. (Jerusalem: Israel Program for Scientific Translations; Springfield, Virginia: US Department of Commerce, National Technical Information Service, 5285 Port Royal Road, 1974.) \$6.

KITAIGORODSKII, S. A. *The Physics of Air-Sea Interaction*. Translated from Russian. Pp.v+237. ISBN-0-7065-1281-2. (Jerusalem: Israel Program for Scientific Translations, 1973.) n.p.

KOVACS, I., and ZSOLDOS, L. *Dislocations and Plastic Deformation*. (International Series of Monographs in Natural Philosophy, Vol. 60.) Pp.xii+343. ISBN-0-08-017062-5. (Oxford and New York: Pergamon Press, 1973.) £3.50.

MARTON, L. (edited by). *Advances in Electronics and Electron Physics*, Vol. 34. Pp.x+362. (New York and London: Academic Press; a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £29.50.

MASSEY, H. S. W., and GILBODY, H. B. *Recombination and Fast Collisions of Heavy Particles*. (Electronic and Ionic Impact Phenomena, Vol. 4.) Second edition. Pp.xxv+2115-3122+38. ISBN-0-19-851253-8. (Oxford: Clarendon Press; London: Oxford University Press, 1974.) £29 net.

MULLER, E. W., and TSONG, T. T. *Field Ion Microscopy, Field Ionization and Field Evaporation*. (Progress in Surface Science, Vol. 4, Part 1.) Pp.viii+140. ISBN-0-08-017779-4. (Oxford and New York: Pergamon Press, 1973.) n.p.

REIMANN, Arnold L. *Physics*. Vol. 3: Modern Physics. Pp.xiv+459+32. ISBN-06-045363-X. (New York: Harper and Row, Inc., 1973.) £3.80.

SCHWINGER, Julian. *Particles, Sources, and Fields*, Vol. 2. Pp.459. ISBN-0-201-06783-8. (Reading, Mass. and London: Addison-Wesley Publishing Company, 1973.) n.p.

SHOTTON, E., and RIDGWAY, K. *Physical Pharmaceutics*. Pp.xiii+409. ISBN-0-19-859708-8. (Oxford: Clarendon Press; London: Oxford University Press, 1974.) £15 boards; £5.75 paper.

STACEY, Jr., Weston M. *Variational Methods in Nuclear Reactor Physics*. (Nuclear Science and Technology: a Series of Monographs and Textbooks.) Pp.viii+181. ISBN-0-12-662060-1. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1974.) £18.50; £9.

SUBE, Ralf und EISENREICH, Gunther. *Physik: Englisch, Deutsch, Französisch, Russisch*. A-M. Pp.1-1026. N-Z. Pp.1027-2012. Register. Pp.2013-2896. (Technik-Wörterbuch.) (Berlin: Veb Verlag Technik, 1973.) 290M.

V. DEINSE, P. A. *Vraagteken bij de Relativiteit van Einstein*. Pp.45. (Utrecht: Uitgegeven door Techniek en Spel, 1974.) n.p.

VAN DEN HANDEL, J. (edited by). *Selected Papers in Physics*. (In Honour of C. J. Gorter.) Pp.xi+359. (Reprinted from *Physica*, Vol. 69, No. 1.) ISBN-0-7204-0289. (Amsterdam: North-Holland Publishing Company, 1973.) Dfl.60; \$21.80.

WALLIS, R. F. *Lattice Dynamics of Crystal Surfaces*. (Progress in Surface Science, Vol. 4, Part 3.) Pp.viii+233-367. ISBN-0-08-017798-0. (Oxford and New York: Pergamon Press, 1973.) £3.50.

WEST, R. N. *Positron Studies of Condensed Matter*. (Taylor and Francis Monographs on Physics.) Pp.123. ISBN-0-85066-070-X. (London: Taylor and Francis, Ltd., 1974.) £3.

Chemistry

BARNES, Dorothy S. *Environmental Chemistry in the Laboratory*. Pp.vii+166. ISBN-0-06-380438-7. (New York and London: Canfield Press, a Department of Harper and Row, Inc., 1973.) £3.25.

BRECK, Donald W. *Zeolite Molecular Sieves: Structure, Chemistry and Use*. Pp.ix+771. ISBN-0-471-09985-6. (New York and London: Wiley-Interscience, John Wiley and Sons, 1974.) £18.

BRIMACOMBE, J. S. (senior reporter). *Carbohydrate Chemistry*, Vol. 6. (A Specialist Periodical Report. A Review of the Literature Published during 1972.) Pp.xii+620. ISBN-0-85186-052-4. (London: The Chemical Society, 1973.) £8.

CHAMBERS, R. D. *Fluorine in Organic Chemistry*. (Interscience Monographs on Organic Chemistry.) Pp.xv+391. ISBN-0-471-14330-8. (New York and London: Wiley-Interscience, John Wiley and Sons, 1973.) £10.75.

CHRISTIE, William W. *Lipid Analysis: Isolation, Separation, Identification and Structural Analysis of Lipids*. Pp.xiv+338. ISBN-0-08-017753-0. (Oxford and New York: Pergamon Press, 1973.) £6.

COFFEY, S. (edited by). *Rodd's Chemistry of Carbon Compounds: a Modern Comprehensive Treatise*. Vol. 3, Part B: Aromatic Compounds. Second edition. Pp.xix+519. ISBN-0-444-40971-8. (Amsterdam, London and New York: Elsevier Scientific Publishing Company, 1974.) Dfl.160; \$58.20.

CROMPTON, T. R. *Chemical Analysis of Organometallic Compounds*. Vol. 1: Elements of Groups I-III. (The Analysis of Organic Materials.) Pp.x+258. ISBN-0-12-197301-8. (London and New York: Academic Press, 1973.) £5.80; \$16.25.

DAUREN, William G. (editor-in-chief). *Organic Reactions*, Vol. 20. Pp.ix+494. ISBN-0-471-19621-5. (New York and London: John Wiley and Sons, 1973.) £12.50.

DOLLISH, Francis R., FATELEY, William G., and BENTLEY, Freeman F. *Characteristic Raman Frequencies of Organic Compounds*. Pp.xviii+443. ISBN-0-471-21769-7. (New York and London: Wiley-Interscience, John Wiley and Sons, 1974.) £12.60.

DREW, Thomas B., COKELET, Giles R., HOOPES, Jr., John W., and VERMEULEN, Theodore (edited by). *Advances in Chemical Engineering*, Vol. 9. Pp.xiii+312. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1974.) £29.50; £13.85.

FACKLER, Jr., John P. (edited by). *Symmetry in Chemical Theory: Application of Group Theoretical Techniques to the Solution of Chemical Problems*. (Benchmark Papers in Inorganic Chemistry.) Pp.xv+508. ISBN-0-87933-018-X. (Stroudsburg, Pennsylvania: Dowden, Hutchinson and Ross, Inc.; Chichester: John Wiley and Sons, Ltd., 1973.) £14.

FLUENDY, M. A., and LAWLEY, K. P. *Chemical Applications of Molecular Beam Scattering*. (Studies in Chemical Physics.) Pp.xi+400. ISBN-0-412-11810-6. (London: Chapman and Hall, 1973. Distributed in the USA by Halsted Press, a Division of John Wiley and Son, Inc., New York.) £8 net.

FREEMAN, Stanley K. Applications of Laser Raman Spectroscopy. Pp. xi+336. ISBN-0-471-17788-6. (New York and London: Wiley-Interscience, John Wiley and Sons, 1974.) £9.75.

FRIEDMAN, Mendel. The Chemistry and Biochemistry of the Sulfhydryl Group in Amino Acids, Peptides and Proteins. Pp.viii+485. ISBN-0-08-016845-0. (Oxford and New York: Pergamon Press, 1973.) £7.50.

GOODISMAN, Jerry. Diatomic Interaction Potential Theory. Vol. 2: Applications. (Physical Chemistry: A Series of Monographs, Vol. 31-2.) Pp. xiii+410. ISBN-0-12-290202-5. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) £34; £16.30.

HAMMES, Gordon G. (edited by). Investigation of Rates and Mechanisms of Reactions. Part 2: Investigation of Elementary Reaction Steps in Solution and Very Fast Reactions. (Techniques of Chemistry, Volume 6.) Third edition. Pp.xiii+665. ISBN-0-471-93127-6. (New York and London: Wiley-Interscience, John Wiley and Sons, 1974.) £15.50.

JANZ, G. J., and TOMKINS, R. P. T. Nonaqueous Electrolytes Handbook, Vol. 2. Pp.xiii+933. ISBN-0-12-380402-7. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1973.) \$60; £28.20.

KATRITZKY, A. R., and BOULTON, A. J. (edited by). Advances in Heterocyclic Chemistry, Vol. 16. Pp.ix+349. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1974.) \$35; £16.80.

LAWLER, R. G. Chemically Induced Dynamic Nuclear Polarization. (Progress in Nuclear Magnetic Resonance Spectroscopy, Vol. 9, Part 3.) Pp. 145-210. (Oxford and New York: Pergamon Press, 1973.) £2.25.

LIM, Edward C. (edited by). Excited States, Vol. 1. Pp.xii+347. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1974.) \$24.50; £11.75.

Fig. 4 Reannealing of DNA reisolated from HeLa cells which had taken up *E. coli* ³H-DNA. HeLa cells (2.5×10^5 cells ml^{-1}) were incubated with $200 \mu\text{g ml}^{-1}$ (Δ) or $0 \mu\text{g}$ (\square) of amphotericin B in the presence of $45 \mu\text{g}$ of *E. coli* ³H-DNA (specific activity $18,400$ c.p.m. μg^{-1}) at 37°C for 30 min. After incubation, cells (15×10^6) were washed and DNA was re-extracted²⁸. DNA was then heat denatured to single strands and DNA-DNA hybridisation was conducted essentially according to ref. 29. In a control experiment a comparable amount of *E. coli* ³H-DNA that had not been exposed to HeLa cells was denatured and its capacity to reanneal with itself was measured (\square). The reaction mixtures each contained $8 \mu\text{g}$ ($1,030$ c.p.m.) of labelled DNA and the specified amount of unlabelled *E. coli* DNA. Another set of control samples was incubated with HeLa cell DNA and a blank filter. The low levels of radioactivity nonspecifically absorbed to the control filters (about 5% of the experimental values) were subtracted from the test samples before calculating the percentage hybridisation.

for the expression of the DNA incorporated into the cells. This work was supported by grants from the US Public Health Service, the John A. Hartford Foundation and the American Cancer Society. We thank Dr Lawrence Gelb for discussions and advice.

Effect of a protein-free diet on mitotic activity of transplanted splenic lymphocytes

THE graft versus host reaction (GVHR) is initiated by donor thymus-derived lymphocytes¹⁻³, and, the defence reaction of the host seems to be influenced by the extent of host lymphoid tissue^{4,5}. Dietary protein deprivation provokes an involution of the lymphoid organs, mainly of the thymus and of the thymus-dependent fraction of blood and lymphoid tissue lymphocytes^{6,7}. It is therefore of interest to know if a protein-free diet given to donors of a spleen graft inhibits the GVHR reactivity of the grafted lymphocytes, and if the same diet given to recipients lowers the capacity of these animals to react against the grafted cells.

The latter hypothesis has already been confirmed⁸. A local lymph node GVHR, produced in hybrid F_1 rats by injection of parental spleen lymphocytes, was reported to be much weaker in protein-deprived recipients than in normally fed ones. In contrast, the weight response of the popliteal lymph node after subplantar injection of lymphocytes from protein-deprived parental rats was not reduced. Here, I report the influence of protein deprivation of donors or recipients on the proliferation of grafted lymphocytes recognised by the Y chromosome.

Adult female (Sherman \times Wistar) F_1 hybrid rats were inoculated intraperitoneally with splenic lymphocytes from male parental (Sherman) rats. The cell suspensions were prepared as described previously⁸. The dose of injected viable cells (unstained by erythrosine) was 120×10^6 or 60×10^6 depending on whether the recipients were fed normally or had been fed on a protein-free diet for the previous two months. (For composition of diet see ref. 9.) The terminal body weight was about 210 g for the normal rats and 105 g for the deficient ones.

The donors also included normally fed and protein-deprived rats. Among the former, 12 rats had been thymectomised at 25 d of age. These were introduced into the study to see whether the thymic atrophy of protein-deprived donors could be responsible for the blocking of the multiplication of grafted cells derived from these rats.

Table 1 Mitoses of donor cells in spleen of recipient rats during first week of a graft *versus* host reaction

Strain and sex Donor	Sex Recipient	Diet		Time since transplantation					
		Donor	Recipient	6 h	6 h	48 h	48 h	7 d	7 d
				Total mitoses ‰ ± s.e.	Donor mitoses ‰ ± s.e.	Total mitoses ‰ ± s.e.	Donor mitoses ‰ ± s.e.	Total mitoses ‰ ± s.e.	Donor mitoses ‰ ± s.e.
Sherman	(Sherman × Wistar) F ₁	Normal	Normal	7.43 ±0.75 (7)	19.93 ±7.05	13.67 ±0.92 (6)	14.51 ±2.08	18.20 ±1.91 (5)	6.93 ±1.99
♂	♀	Normal	Protein-free	1.71 ±0.03 (7)	0	7.50 ±0.99 (6)	11.00 ±4.30	8.67 ±1.98 (6)	17.67 ±3.80
♂	♀	Protein-free	Normal	6.00 ±0.38 (7)	12.23 ±3.73	15.50 ±1.77 (6)	0	19.33 ±2.73 (6)	0.93 ±0.93
♂	♀	Protein-free	Protein-free	—	—	7.17 ±0.70 (6)	6.36 ±0.94	11.40 ±3.04 (6)	21.00 ±3.67
Thymect. Sherman ♂	♀	Normal	Normal	4.71 ±0.36 (7)	0.79 ±0.79	9.00 ±1.61 (5)	9.16 ±5.67	—	—
Sherman ♂	Sherman ♀ (Syngeneic controls)	Normal	Normal	—	—	9.60 ±0.93 (5)	2.00 ±1.23	4.75 ±0.85 (5)	—
Uninjected Sherman ♀		Normal		—	—	4.00 ±0.63 (5)	—	—	—

Values are means ± s.e. The numbers of rats are indicated in parentheses. All recipient rats had been injected intraperitoneally 1 h 30 min before killing with 0.25 mg per 100 g of colchicine. The total number of mitoses was established on chromosomal preparations performed according to ref. 13 and stained with Unna's Blue. The percentages of mitoses of the male donor cells were counted after construction of karyotypes from 100 selected mitotic figures.

The F₁ recipients were killed 6 h, 48 h or 7 d after the transplantation. Uninjected female Sherman controls or female Sherman rats injected with 120 × 10⁶ male Sherman lymphocytes and killed after 48 h or 7 d were also studied to exclude GvHR-independent mitotic activity.

As shown in Table 1, normally fed F₁ recipients inoculated with normal parental lymphocytes exhibited a progressive increase in the mitotic index between days 1 and 8, whereas the percentage of male (donor) mitoses dropped from about 20 to 7. These results agree with already published reports¹⁰⁻¹² indicating that cellular proliferation in the spleen, induced by GvHR, is mainly of host origin. In normal recipients inoculated with lymphocytes from protein-deprived donors, the total number of mitoses per 10³ cells showed the same changes as in the above group but the mitoses of the grafted cells disappeared almost completely after 48 h and 7 d. As shown by the total number of mitotic figures, the host reaction was at least as important as after inoculation of normal parental lymphocytes.

If the protein-free diet was given not to the donors but to the recipients, splenic mitoses were much less numerous than in normal recipients although their number increased between days 1 and 8. No donor cell mitoses were detected 6 h after transplantation but the initial inhibition of the grafted cells was only temporary and after 7 d the number of male mitoses became even significantly higher in protein-deprived than in normal recipients. Since the proliferation of the parental lymphocytes seems to be conditioned by continuous stimulation exercised by alloantigens of the host cells¹², it seems that the latter cells preserve their capacity of stimulating the donor lymphocytes, although (partly) losing their ability to defend themselves against their aggressors.

If both donors and recipients were deprived of proteins, the total number of mitotic figures was as low as in the preceding group, although higher than in uninjected rats. But the multiplication of donor cells from protein-deprived parents was not at all impaired after contact with cells of protein-deprived recipients while it was, as seen above, inhibited by lymphocytes of normally fed F₁ hybrids.

The inability of lymphocytes from protein-deprived donors to divide in the spleen of normal recipients could not be attributed exclusively to the low content of the graft in GvH-reactive T

lymphocytes because of the thymic atrophy of the donors. Indeed, if the transplanted lymphocytes came from normally fed but thymectomised parental rats, the multiplication of these cells in the recipients, although completely inhibited in all rats during the first hours and in some rats even 2 d after inoculation, reached normal levels in other rats after 2 d. Since thymic atrophy cannot be more harmful than late thymectomy, it may well be that the suppression of mitotic division of cells from protein-deprived donors may be due to inactivation of donor B lymphocytes as well as to inactivation of T lymphocytes.

Assuming that the GvHR-initiating role of the donor T cells consists in the recognition of foreign histocompatibility antigens of the host¹², and that this recognition is followed by production of antibodies by donor B lymphocytes against these antigens, it may be that protein deprivation of donor rats does not completely impair the capacity of their T lymphocytes to recognise alloantigens but that the immunological response of their B cells is prevented. This naturally facilitates the host reaction against the grafted lymphocytes, from protein-deprived donors, which may explain the blocking of proliferation of the latter cells.

I thank D. Soulas (Centre National de la Recherche Scientifique) and M. T. Guilbaud (INSERM) for technical assistance.

Neutral evolution and immunoglobulin diversity

THE origin of immunoglobulin diversity and species specificity continues to be a controversial topic. Proponents of the germ line theory have presented a limited gene expansion-contraction model in general terms¹⁻³; the mechanism has not yet been demonstrated to produce sufficiently rapid changes in a multi-gene system to account for the observed phenomena. Species divergence of immunoglobulin *V* regions continues to be cited as strong evidence against multiple germ line *V* genes^{4,5}. We report here computer simulation of random unequal crossing over within a system of multiple related genes and compare the results with the relationships observed between immunoglobulin *V* region sequences from different species. We conclude that the species-specific features of immunoglobulin *V* regions can arise as a result of such random processes operating in the multigene set.

We assume that the previous evolutionary history of the organism established a set of genes by repeated duplication and accumulation of point mutations such that the individual genes are homologous but not necessarily identical. The homology is compatible with continued unequal crossing over. This event and its consequences are illustrated in Fig. 1. In the absence of any meiotic distortion the probability of the progeny receiving a chromosome with one additional gene or with one less gene is equal. In the absence of selective pressures, the new duplication or deletion, in itself, would represent a neutral mutation and as such would become fixed in the population at a rate equal to the rate of occurrence of the event⁶.

We simulated the evolution of 50 related genes by unequal crossing over in the absence of selection. At each step of an iterative process, a gene occupying one of the positions in the linear array was selected on a random basis and was either duplicated in the array or deleted. At each event, only the duplicated or the deleted product was chosen at random and was then assumed to become fixed in the population as a neutral mutation before the next repetition. Figure 2 is the result of 200 repetitive cycles. Comparison of the evolved sequence with the initial sequence shows that some of the original genes have been eliminated and replaced by duplications of other original genes. The consequence is evolution of subgroups of closely related genes within a set of related genes. Point mutations and single codon additions or deletions will occur within genes of a subgroup during its evolutionary history. These events and the structure of the ancestral gene of each subgroup will give the characteristic features of the subgroup and provide variation within the individual members.

Speciation divides a common gene pool and permits random mutational events to act on the two resulting pools in an independent manner. This was simulated by taking the original set of 50 related genes and repeating the 200 cycles of unequal cross overs under separate random control. Figure 3 compares the results of independent evolution of the two gene pools. In most cases, the remaining genes in the second example differ from those in the first as do the subgroups and their distribution. Speciation and subsequent independent evolution by this mechanism in the absence of any selective forces does permit multiple homologous but nonidentical genes to evolve and produce species-specific subgroups which have descended from different ancestral genes.

The simulation has been presented in terms of 50 genes;

Fig. 1 Unequal crossing over between tandem sets of homologous genes and the products of the event.

however, the results are valid for larger sets, as shown in Fig. 4. Within the limits of the random process, the number of cross overs required for any given reduction in number of subgroups is directly proportional to the number of original genes. For example, 250 genes are reduced by 60% after 600 cross overs while 500 genes are reduced by 60% after 1,200 cross overs. Fifty genes are reduced to 1 subgroup after 2,000 cross overs and by extrapolation 1,000 genes would be reduced to 20 subgroups after 40,000 cross overs.

The number of subgroups present in any species will depend on the number of unequal cross overs which have been established following speciation (Fig. 4) and will also vary due to the random nature of the events involved. The model anticipates different numbers of subgroups in different species, such as appear to exist in mouse and human kappa chains^{1,7}. Although the total number of *V* genes tends to remain at a constant average level, random fluctuations about this mean value occur during any one simulation. The model could thus account for the differences in the proportion of kappa to lambda chains observed in different species. Similarly, variations in the proportions of the heavy chain subgroups in different species are expected⁴.

Fig. 2 The origin of subgroups by unequal crossing over. The top set of numbers represent 50 homologous but nonidentical genes arranged in tandem order. Gene deletion and duplication was simulated as shown in Fig. 1 with random selection of the gene involved and of the deleted or duplicated product. After 200 unequal cross overs the bottom set of numbers was obtained.

The model as presented in its simplest form can account for many of the documented facts concerning the evolution of *V* region sequences⁷. The model depends on cross overs which are ubiquitous genetic events⁸. Once the initial unequal cross over has taken place in the multiple gene system, subsequent recombinations involving either the deleted or duplicated product will also be unequal and the process will be self propagating⁹. The frequency of unequal crossing over could approach the frequency of recombination which has been estimated to be 2×10^{-3} for two markers separated by 1,000 tandem *V* genes¹. If the average mammalian generation time is 4 yr¹⁰, one neutral unequal cross over would be established every 2,000 yr where the rate of fixation is equal to the rate of occurrence⁶. If the kappa *V* gene pool contains 1,000 genes, the data in Fig. 4 suggest that 40,000 cross overs would be required to establish the present species divergence between mouse and human kappa

Fig. 3 The effect of speciation on evolution by unequal crossing over. The top set of numbers are the product of 200 simulated cross overs as shown in Fig. 2. Speciation was simulated by taking the original set of 50 numbers and repeating the 200 unequal cross overs under separate random control. The bottom set of numbers is the result of the second series of unrelated random processes.

chains. This would take 8×10^7 yr which is the time estimated for evolution of the primates¹¹. The model is therefore compatible with a pool size of 1,000 genes and the evolutionary time scale.

Although the model has been tested in the absence of any selective pressures, it is obvious that these must exist. Simple determinants elicit production of several variable region sequences which suggests that considerable redundancy or degeneracy exists in the immune system¹²⁻¹³. A single V region sequence with the unique capacity to combine with a given pathogenic determinant⁷ is probably rare. We feel that the major role of selection will be to prevent deletion of the final copy of certain genes essential for immunological survival of the species in its indigenous pathogenic environment. Deletion of the corresponding gene would be lethal. Simulation of this situation gives a result which is not significantly different from the simulation without selection.

The model does not require extensive reduction or increase in gene number within the multiple gene system during evolution. Therefore, a fully functional immunological system will be available to the evolving species at all times. The past immunological experience of the species will be contained in the gene copies and may be subject to gradual elimination only if these genes are of no selective advantage to the present phenotype. The model permits a response to present immunological challenges based on past experience while maintaining adequate options to meet future attacks.

Fig. 4 The effect of the number of unequal cross overs and size of the initial gene set on the number of subgroups. The number of subgroups are expressed as a percentage of the original number of genes in the set. Δ , 50 initial genes; \bullet , 250 initial genes; \circ , 500 initial genes; \blacksquare , 1,000 initial genes. The star represents the convergence of all four curves at 100%.

Note added in proof. Smith (Cold Spring Harbor Symp., in the press) has also used computer simulation to reach conclusions similar to those presented here.

Surface antigen(s) common to human astrocytoma cells

SINCE animal tumours induced by viruses exhibit common antigenic properties¹, the extent to which antigens are shared in human tumours is of obvious interest. Such antigenic cross reactions between human tumours of the same histological origin have been demonstrated by cell-mediated colony inhibition testing as well as by serological means^{2,3}. But few immunological studies of human brain tumours have been reported. Studying the cytotoxic effect of patients' lymphocytes on autologous or allogeneic astrocytomas, some workers have found antigenic cross reaction⁴ while others have not⁵. I report here the serological demonstration of surface antigen(s) common to cultured human astrocytoma cells.

Surgically removed human cerebral tumours were mechanically disaggregated and maintained in HEPES-buffered Eagle's Minimum Essential Medium with Earle's salts, 10% horse serum, 5% foetal bovine serum, glucose (3 mg ml⁻¹), glutamine (0.3 mg ml⁻¹), penicillin (50 units ml⁻¹), streptomycin (50 µg ml⁻¹) and Fungizone (2.5 µg ml⁻¹) (M. S. Lakshmi, personal communication.) The cells used for immunisation were those designated Astrocytoma 301, cultures of which were shown to be mycoplasma- and virus-free and of glial morphology by electron microscopy. The cells were collected in EDTA (0.02%) and washed in phosphate-buffered saline (PBS), pH 7.2. A New Zealand white rabbit was injected intravenously with 25×10^6 cells on days 0 and 14, and bled out on day 24. The serum was heated for 30 min at 56° C and its antibody activity assayed by dye exclusion cytotoxicity testing⁶ using cultured astrocytoma cells as targets and guinea pig serum as the source of complement. The antiserum was repeatedly absorbed with normal brain homogenate until further absorptions did not decrease the cytotoxicity against Astrocytoma 301 cells. This required four absorptions (Fig. 1a).

Brain homogenate was no more effective in decreasing cytotoxic activity than liver, spleen, kidney, myocardium or thyroid homogenates (Fig. 1a, b). On a volume per volume basis, brain was no more efficient in absorbing the original

Fig. 1 Dye exclusion cytotoxicity tests showing the activity of unabsorbed anti-astrocytoma 301 serum (●—●) and of the antiserum absorbed *a*, $\times 4$ or *b*, $\times 6$ with human brain (■—■), liver (●—●), spleen (○—○), kidney (□—□), heart (△—△) and thyroid (▲—▲). Astrocytoma 301 cells, between third and sixth passage were collected in EDTA (0.02%), washed and suspended in phosphate-buffered saline (pH 7.2) with 0.1% bovine serum albumin (PBS) at 10^6 cells ml^{-1} . 25 μl of cells were incubated with 25 μl of doubling dilutions of antiserum for 30 min at 37°C ; after washing once, cells were resuspended in fresh unabsorbed guinea pig serum diluted 1:4 in PBS for 30 min at 37°C following which the number of dead cells was assessed using trypan blue staining. For absorption, tissues were homogenised in a Potter-Elvehjem homogeniser, and washed $\times 3$ in PBS. The antiserum was mixed with equal volume of packed homogenate (centrifuged $3,600g \times 10$ min) and absorbed for 30 min at 20°C with continuous shaking. ●, Normal serum; ○, complement.

‡ Established line.

§ Doubling dilutions of 25 μl packed homogenate were used. Controls were used as in Figs 1 and 2.

antiserum than other tissues tested; it is therefore unlikely that there were any brain-specific antibodies in the original serum. Since the absorbed antiserum could not be further absorbed by a number of nonastrocytoma cells, but could be completely absorbed with cultured cells from each of seven different astrocytomas (Fig. 2, Table 1), I shall refer to the antigen(s) defined by it as human astrocytoma-associated antigen(s) (HAAA). When target cells were collected mechanically, by treatment with EDTA (0.02%) or trypsin (0.02%), similar results were obtained. Absorption of anti-HAAA activity by homogenates of two original astrocytoma (301 and A3) samples, stored at -165°C , indicates the presence of this antigen *in vivo*.

In view of the failure of cultured cells from foetal brain or normal brain homogenates to absorb the anti-HAAA activity (Fig. 2, Table 1) it seems unlikely that HAAA is an

Fig. 2 Dye exclusion cytotoxicity tests showing the ability of cultured cells from seven different astrocytomas, A1 (●—●), A2 (○—○), A3 (▲—▲), A4 (△—△), A5 (■—■), A6 (□—□), and 301 (▼—▼) and homogenates of 301 (▼—▼) and A3 (▲—▲) to absorb anti-HAAA activity. Results of absorptions with various non-astrocytoma cells and homogenates fall within the cross-hatched area and are given in detail in Table 1. 25 μl of anti-HAAA diluted 1:12 in PBS was absorbed with doubling dilutions of a suspension of whole cells or homogenates (50% v/v) for 30 min at 37°C and the absorbed serum tested as in Fig. 1, with unabsorbed rabbit serum diluted 1:10 as complement.

oncofoetal antigen or an astrocyte differentiation antigen, although the former cannot be entirely excluded since HAAA expression could be restricted to a stage of embryogenesis not represented by the samples available here. It is also possible that absorption with normal adult brain tissue from more individuals would reveal that HAAA is normally expressed in a proportion of normal brains, making it an alloantigen analogous to the thymus-leukaemia (TL) antigen in mice⁷. The exact significance of the common antigen detected here remains in doubt but could suggest a common viral aetiology.

The data suggest that appropriately absorbed heteroantisera may be useful tools for defining surface antigens of human tumours, as they appear to be for some cytoplasmic antigens⁸. The demonstration of HAAA might stimulate renewed attempts at immunotherapy for gliomas⁹.

I thank Professor K. R. Rees of the Department of Biochemical Pathology, University College Hospital Medical School and Dr M. Raff of the Neuroimmunology Project, Department of Zoology, University College London, for advice; and Mr B. J. Harries and Mr I. R. McCaul of University College Hospital and the Whittington Hospital, London, for surgical material. This work was supported by the Cancer Research Campaign.

Potent luteolytic agents related to prostaglandin F_{2α}

EXPLOITATION of prostaglandin F_{2α} (PGF_{2α}) and E₂ (PGE₂) for the regulation of fertility in man and animals is limited by their side effects. Luteolytic agents which are much more potent than PGF_{2α}, without being correspondingly more toxic, have been found among the many analogues of this prostaglandin synthesised in these laboratories, notably among compounds of general structure I (ref. 1). We present here results obtained with three compounds—ICI 79,939, ICI 80,996 and ICI 81,008—which illustrate the variations in biological activity in this series.

The luteolytic activity of these compounds was assessed from their capacity to terminate pregnancy on administration (in phosphate buffer, pH 7.4) to hamsters and rats. They seem to be ineffective in this respect when given to hamsters before day 4, or rats before day 5 of pregnancy (vaginal sperm = day 1). But, when given subcutaneously (s.c.) to hamsters on days 4, 5 and 6, ICI 79,939 and ICI 80,996 are 200 times, and ICI 81,008 is 100 times as potent as PGF_{2α} in terminating pregnancy, as judged by the absence of embryos from the uterus at autopsy on day 8. The fully effective daily dose of ICI 79,939 or ICI 80,996 is 0.125 µg (~ 1.25 µg kg⁻¹), and this same dose is equally effective given only once on day 4. The potencies of the analogues are comparable whether given by intraperitoneal (i.p.) or subcutaneous (s.c.) injection. By mouth, the analogues (given on days 4–6) are only 1/20, and PGF_{2α} 1/40 as potent as when given s.c.

These substances are much less effective in interrupting early pregnancy in rats. Administration of an s.c. dose, at ~ 1700 h on day 5 and again at ~ 1000 h and 1700 h on day 6 proved to be

ICI 79,939	R ₁ =F;R ₂ =H (racemic)
ICI 80,996	R ₁ =H;R ₂ =Cl (racemic)
ICI 81,008	R ₁ =H;R ₂ =CF ₃ (racemic)

most effective as judged by the absence of implants at autopsy on day 9 and 11. Minimum fully effective doses (MFED) in groups of six rats are shown in Table 1a.

On this basis ICI 79,939 is ~ 200 times, and ICI 80,996 and ICI 81,008 are 100 times as potent as PGF_{2α} in rats.

In both hamsters and rats given effective doses of these analogues, daily administration of progesterone (4 mg, s.c.) maintains pregnancy. Moreover, in rats given a single dose of ICI 79,939 (10 µg) or ICI 80,996 (25 µg) on day 6 of pregnancy, reductions in plasma progesterone of over 60% were found 6 h later. We conclude that these substances owe their effect on early pregnancy in both species to luteolysis.

Administration of the analogues to rats in early pregnancy also results, within 48 h of the first dose, in the appearance of nucleated and/or cornified cells in the vaginal smear which is probably due to a decline in progesterone levels. It is seen also in intact or hysterectomised pseudopregnant rats dosed on day 6 and 7 of pseudopregnancy (oestrus = day 1) with ICI 80,996 (2.5 µg, s.c.) or ICI 81,008 (10 µg, s.c.). This also is attributed to the luteolytic action of the compounds which thus seems to be independent of the presence of embryos in the uterus—and even of the uterus itself.

Rats are more sensitive to PGF_{2α} (ref. 2) and the analogues around day 9 of pregnancy, when effective doses cause foetal resorption, and on day 19 or 20 when even smaller doses induce premature parturition. (Table 1b and c. Rats dosed on day 9 were autopsied on day 18. In rats dosed on day 20, parturition was taken to be premature if they littered before 1100 h on day 22—our rats normally litter between the afternoons of days 22 and 23.)

It will be seen that the relative efficacy of PGF_{2α} and the analogues at these later stages of pregnancy in rats is similar to their relative luteolytic potency in early pregnancy in hamsters and rats. Moreover PGE₂ which is a weak luteolytic agent³ but very potent smooth muscle stimulant (Table 2) has to be given in a very high dose (Table 1) to cause rats to litter prematurely. It is probably, therefore, by virtue of their luteolytic

Table 1 Doses of PGF_{2α}, its analogues, and PGE₂ required to interrupt pregnancy in rats.

Compound	MFED (µg kg ⁻¹ : total)

Bringing automatic chemistry down to size

The ABA.100 will provide your laboratory with a fully automatic discrete and highly flexible clinical chemistry analyser, which combines high workload capacity with high resolution spectrophotometry, both U.V. and visible.

Speed
10 to 150 samples per hour.

Ease
Automatic processing, data handling and print out.

Convenience
Kinetics and end points, 30° or 37°C,* unit conversions, increasing or decreasing absorbance measurement the flick of a switch.

Accuracy & Precision

C.V.'s typically better than 2% in the normal range.

Temperature maintained to within $\pm 0.1^\circ\text{C}$.

Automatic reagent blank correction.
Data-calculations and conversions performed by integral mini-computer.
Conversion directly into IU/l or mgm.

Automatic warning of non-linear rate reactions.

Economy

Saves substrate—uses as little as 250 μl .

Saves serum—uses as little as 5 μl .

Saves time—30 glucose in 10 minutes.

Saves space—only 4 cubic feet of bench space.

* 25°C AVAILABLE.

Coulter Electronics Limited,
Coldharbour Lane, Harpenden,

COLD SPRING HARBOR LABORATORY

COLD SPRING HARBOR CONFERENCES ON CELL PROLIFERATION, VOLUME 1

CONTROL OF PROLIFERATION IN ANIMAL CELLS

EDITED BY

Bayard Clarkson, *Sloan-Kettering Institute for Cancer Research*

Renato Baserga, *Temple University School of Medicine*

With the publication of this book all can profit from the information imparted and lively communication engendered at the first in a series of annual Conferences on Cell Proliferation to be held at Cold Spring Harbor Laboratory.

The resulting 79 papers contained in this volume provide a comprehensive overview of the basic aspects of proliferation in both normal and abnormal cells with the emphasis on the most recent findings of importance.

1974, 1035 pp., illus, index \$30, clothbound ISBN: 0-87969-111-5

CONTENTS

Growth Factors

Environmental pH and Cellular Metabolism (Eagle); Serum Factors (Holley); Multiplication-stimulating Activity (Temin); Migration Factor (Burk); Liver DNA Replication (Short); Enzyme Induction (Argyris); Estrogen and Cell Proliferation (Bresciani); Steroid Induction of mRNA (O'Malley); Hormones and Mammalian Cell Growth (Armelin); Glucocorticoids (Cunningham); Hormonal Control (Sibley)

Viral Transformation, Revertants, and Mutants

Revertants of SV40-transformed 3T3 (Vogel); Classes of SV40-transformants (Risser); SV40 Integration and DNA Synthesis (Hirai); Host Cell Control of Viral Transformation (Basilico); ConA-resistant SV3T3 Cells (Ozanne); Mammalian Cell Synthetase Mutant (Stanners); BrdU Dependence in Mammalian Cells (Davidson)

The Cell Surface

Antigen Mobility in Fibroblasts (Edidin); Displacement of Surface Components (Stackpole); Membrane Particle Arrays (Satir); Dynamic Display of Lectin Binding Sites (Nicolson); Distribution of ConA Receptors (Raff); Mobility of Membrane Receptors (Sachs); Agglutinability of Mitotic Cells (Shoham); Fibroblasts Surface and Growth Control (Vaheri); The Transformed Cell Surface (Talmadge); Growth Inhibition by Protease Inhibitors (Schnebli); Protease Inhibitors and Cell Growth (Chou); Tumor-associated Fibrinolysis (Reich); Lymphocyte Surface Alterations (Edelman); Proliferation in the Immune System (Fahey); IgM in B Lymphocytes (Melchers); Regulation of the Immune Response (Diener); Hormone Receptors and Mitogenesis (Hollenberg); Ricinus Agglutinins (Kornfeld); Plasma Membrane Interactions (Allison); Cell Behavior and Surface Structure (Hakomori); Cell Cycle Synthesis of Glycolipids (Wolf); Glycolipids of Hamster

Cells (Critchley); Lipids of Semliki Virus (Renkonen); Gangliosides in Transformed Cells (Brady); Studies of Normal and Transformed Cells (Grimes); Galactosyltransferase Intermediates (Dorsey); Rous Transformation of Chick Cells (Wickus)

Biochemistry of the Cell Cycle

Membrane Function and Growth (Pardee); cAMP and Malignant Transformation (Pastan); cAMP and Cell Proliferation (Sheppard); cAMP and Differentiation of Neuroblastoma Cells (Prasad); cAMP and DNA Synthesis in Parotid (Durham); Control by cGMP and cAMP (Goldberg); Phorbol Myristate Acetate and cGMP (Estensen); cAMP, cGMP in Epidermal Proliferation (Voorhees); Hormonal Regulation and cAMP (Makman); Sequential Cell Cycle Events (Tobey); Nuclear Protein Phosphorylation (Allfrey); HeLa Histone Modification (Borun); Histone Phosphorylation and Cell Replication (Chalkley); Antibodies to Chromatin (Zardi); Ribosomal RNA during Transition to Growth (Green); RNAs in Growing and Nongrowing Cells (Birnie); Poly (A)-RNA in Lymphocytes (Cooper); Cell Cycle in Hybrid Cells (Rao); Glycolysis, Sugar Transport, and DNA Synthesis (Rubin); Periodic DNA Amplification (Klevecz)

Proliferation Kinetics, Differentiation, and External Influences

Self-Regulation of Growth (Folkman); Proliferation in Development (Topper); Erythroid Cell Proliferation (Marks); Differentiation in Erythroleukemia (LoBue); Colony-stimulating Factor (Metcalfe); Hemopoietic Cells in Culture (Till); Differentiation of Hematopoietic Cells (Sachs); Hemopoietic Inductive Microenvironments (Trentin); Regulatory Mechanisms of Marrow Stem Cells (Tubiana); Survival Value of the Dormant State (Clarkson); Comparison of Proliferation (Lamerton); Mammalian Cell Cycle Radiation Response (Sinclair); Cytotoxicities of Combinations (Wheeler); Summary: Signals and Switches (Stoker)

activity that these compounds interrupt pregnancy at all stages in the rat.

The luteolytic potency of these agents is, however, in no way related to their capacity to stimulate smooth muscle. This was assessed *in vitro* from their potency in provoking isotonic contractions of the isolated uterus of dioestrous guinea-pigs and of segments of gerbil colon (Table 2).

As a smooth muscle stimulant, ICI 80,996 is similar in potency to PGF_{2α}, whereas ICI 79,939 is 10 times, but ICI 81,008 only 1/50 as potent.

In general, the severity of the side effects of these compounds parallels their potency as stimulants of smooth muscle. With ICI 79,939, early pregnancy can be terminated in hamsters and even in rats at doses that have no obvious side effects: these doses, however, are toxic to nonpregnant animals and sometimes lethal to young ones. In the doses needed to interrupt pregnancy in these species, ICI 80,996 and ICI 81,008 seem completely devoid of side effects in both pregnant and nonpregnant animals. Moreover, large multiples (× 20 or more) of these doses can be given without causing serious distress. With PGF_{2α}, side effects are sometimes seen at doses below the minimum required to terminate pregnancy. When seen, the side effects of the analogues are similar to those of PGF_{2α} and include watery diarrhoea, hypersalivation, gasping, abdominal 'squirming', ataxia, reduced motility, irritability and weight loss.

Table 2 Relative potencies of PGF_{2α}, its analogues and PGE₂ in stimulating contractions of smooth muscle *in vitro*

Compound	Guinea pig uterus	Gerbil colon
PGF _{2α}	1 (assigned)	1 (assigned)
ICI 79,939	10	9.5
ICI 80,996	1	0.6
ICI 81,008	0.02	0.036
PGE ₂	36	—

From our results it seems that, while the analogues described are similar in luteolytic potency and all are many times as potent as PGF_{2α}, they differ markedly as smooth muscle stimulants and in toxicity. By the criteria described above, ICI 79,939 is more toxic than PGF_{2α}, ICI 80,996 less toxic, and ICI 81,008 very much less toxic.

Reports have already appeared on the luteolytic activity of these analogues in farm animals^{4,5} and their potential for the control of oestrus and the treatment of infertility in cattle⁴ and horses^{5,6} and the induction of farrowing in pigs⁷. Results in pig-tail monkeys (*Macaca nemestrina*) suggest that ICI 80,996 and, more particularly, ICI 81,008 may also be of value as antifertility agents in women. A s.c. dose of 50 µg kg⁻¹ of ICI 80,996 or 100 µg kg⁻¹ of ICI 81,008 given on day 20 of the (30–31 d) cycle and on the next 4 to 5 d, causes menstrual bleeding 4 to 7 d before the expected time. The rapid fall in plasma progesterone during treatment and before the onset of bleeding indicates that this is due to luteolysis. Several of the monkeys given ICI 80,996 suffered transient side effects, chiefly diarrhoea, but with ICI 81,008 these were infrequent and mild.

We thank P. H. Atkinson, R. Chester, B. Valcaccia and A. J. Vernall for assistance, G. Smith for progesterone assays and Dr N. S. Crossley and his colleagues for providing the compounds.

Potent bronchoconstrictor activity of 15-keto prostaglandin F_{2α}

THE effects of parent prostaglandins (PG) on bronchial muscle *in vitro*¹⁻³ and *in vivo*^{4,5} have been characterised, but the pharmacological properties of their metabolites are less well defined. The lung is an important site of PG metabolism and a better understanding of the effects of the various metabolites is necessary since PGs are now recognised as compounds released in asthma. Modification of PG metabolism itself could be responsible for the aetiology of the asthmatic bronchospasm, particularly since asthmatic subjects have been shown to be considerably more sensitive to inhaled PGF_{2α} than the normal population⁶. We have shown that 15-keto PGF_{2α} possesses very potent bronchoconstrictor activity and is probably important in asthma.

Two enzymes in the lung are responsible for metabolising PG: 15-hydroxy prostaglandin dehydrogenase, which converts, for example, PGF_{2α} to 15-keto PGF_{2α} and 13:14 prostaglandin reductase which reduces 15-keto PGF_{2α} to dihydro-15-keto PGF_{2α}. In lung from most species, these enzymes are closely related and the intermediate, 15-keto PGF_{2α} is not seen in the tissue or in the blood leaving the lung.

Dihydro-15-keto PGF_{2α}, the usual metabolite formed from PGF_{2α} has been shown to have little spasmogenic activity on many tissues⁷ but the data on 15-keto PGF_{2α} (ref. 8) are incomplete.

15-keto PGF_{2α} was synthesised from PGF_{2α} by oxidation with activated manganese dioxide⁹ and purified by column and plate chromatography; its structure was confirmed by nuclear magnetic resonance and mass spectrometry. Biosynthesis using homogenates of swine lung¹⁰ followed by similar purification gave the same compound.

15-keto PGF_{2α} was assayed biologically *in vitro* on guinea pig ileum, guinea pig tracheal chains, rat colon, stomach strip and uterus, rabbit aortic strips, gerbil colon and human bronchial muscle strips. Table 1 shows the relative potencies of PGF_{2α} and 15-keto PGF_{2α} on these tissues, indicating that 15-keto PGF_{2α} is more potent than PGF_{2α} on most preparations. Synthetic and biosynthetic 15-keto PGF_{2α} were equally active in each test.

PGD₂, an isomer of PGE₂ and 15-keto PGF_{2α}, was a potent bronchoconstrictor substance, having the same order of potency as PGF_{2α}. This suggests that the 9-hydroxyl group is necessary

¹ Binder, B., Bowler, J., Brown, E. D., Crossley, N. S., Hutton, J., Senior, M., Slater, L., Wilkinson, P., and Wright, N. C. A., *Prostaglandins*, **6**, 87, (1974).

for bronchoconstrictor activity but substitution in the 15 position is less critical. Uncharacteristic responses are, however, occasionally produced by most prostaglandins and although PGE₂ is usually bronchodilator, it sometimes causes bronchoconstriction (H. O. J. Collier and P. Gardiner, symposium on Bronchodilator Drugs, Royal College of Physicians, 1 October, 1973).

All three isomers have been isolated from bovine lung perfusates following immunological challenge. The contraction of both human bronchial muscle strips and guinea pig ileum produced by 15-keto PGF_{2α} is similar in character to that of slow-reacting substance in anaphylaxis (SRS-A), although the substances can be separated by chromatography.

Table 1 Effect of 15-keto PGF_{2α} relative to PGF_{2α} on various isolated smooth muscle preparations

Pharmacological isolated preparation	Relative potency of 15-keto PGF _{2α} (PGF _{2α} = 1)
Guinea pig ileum (11)	2–4
Gerbil colon (11)	5–10
Guinea pig trachea (12)	2–3
Human bronchial muscle (3)	1–2
Rat colon (11)	1–2
Rat stomach strip (11)	0–3*
Rat uterus (11)	0.1–6*
Rabbit aortic strip (11)	†

* Variable responses, with no apparent relationship to concentration.

† No response to either.

Figures in brackets indicate references to methods used.

The belief that prostaglandins are of importance in asthma³ is greatly strengthened by this work, which suggests a definitive involvement of PGs and their metabolites in the asthmatic bronchospasm. Further work to establish the role of 15-keto PGF_{2α} and other metabolites is in progress.

We thank Dr R. G. Harrison for the preparation of synthetic 15-keto PGF_{2α}, Mr J. R. Boot for PGD₂ and 15-keto PGF_{2α} and Mr J. W. Jackson and Sister J. DeMulder of Harefield Hospital, Middlesex for their help in obtaining specimens of human lung.

Origin of asymmetry in biomolecules

ONE of the most exciting hypotheses put forward to explain the molecular asymmetry of living beings is based on a physical concept, the 'parity nonconservation law'¹. According to this, matter is intrinsically asymmetric (β particles are always spin polarised) and the molecular asymmetry on Earth is a reflection of the structure of matter itself^{2–5}. Though the theory is attractive, experimental results are controversial. Some people have reported differences in the radiation susceptibility of the two enantiomers (D and L forms) of a molecule if irradiated with β^- particles and/or their associated circularly polarised γ rays (bremsstrahlung)⁶, whereas others have failed to detect any differential radiolysis in similar experiments⁷. One possible explanation for the controversial data may be that the decomposition of molecules depends on many factors which may mask the expected differential interaction between β^- particles and optical isomers. To avoid these disturbing factors, we studied the annihilation of β^+ particles in optical isomers, exploiting the great advantage of this technique that it gives information about the interaction process itself rather than about the products of interaction.

The purity of the samples used throughout the experiments was checked by conventional methods. On paper chromatograms with different solvent systems each gave one spot. The absorption, CD and luminescence spectra of the enantiomers were the same between the limit of experimental errors. Sodium-22 was used as the positron emitter. Crystalline D and L amino acids were packed around the ²²Na source (activity 0.8 μ Ci) to a thickness of 6 to 7 mm, and it was placed between two scintillation counters of NE111 plastic phosphor coupled to AVP56 photomultipliers. Conventional electronic circuits selected coincidences between the 1.28-MeV γ radiation of the ²²Na and the 0.51-MeV annihilation radiation produced in the crystals of the two enantiomers. The positrons annihilate on free electrons with a short lifetime⁸ ($\tau \sim 2 \times 10^{-10}$ s) and may form positroniums in singlet ($\tau_s \sim 1.2 \times 10^{-10}$ s) and triplet states ($\tau_t \sim 2.7 \times 10^{-7}$ s) with bound electrons. The triplet positroniums do not, however, live as long in condensed matter, because they transform to the singlet state by the so-called 'pick-off' mechanism with a lifetime of $\tau_{t'}$ ~ 1 to 50×10^{-9} s and annihilate from this state into two photons giving 0.51-MeV γ rays. The time delay was measured by a time-to-amplitude converter and multichannel analyser.

Table 1 Triplet intensity in L and D isomers; data from positron annihilation time spectra

Material	No. of independent runs	L	D	D/L
Phenylalanine (Calbiochem)	8	11.0 (6)	13.4 (6)	0.83 (6)
Tyrosine (Sigma Chemical Corp.)	8	4.4 (2)	4.7 (2)	0.94 (6)
Dihydroxy-phenyl-alanine (Nutritional Biochemical Corp.)	4	1.6 (1)	2.2 (1)	0.72 (6)
Tryptophan ¹ (Nutritional Biochem. Corp.)	4	12.0 (1)	18.0 (1)	0.67 (7)
Tryptophan ² (Koch-Light Laboratories Ltd)	4	18.8 (10)	22.8 (10)	0.82 (5)

The results are summarised in Table 1. There are clearly significant differences in triplet annihilation intensity between L and D amino acids. In other words the experiments show that the D isomers of amino acids favour triplet states in case of forward polarised β^+ particles.

It seems likely from this evidence that β decay was the cause of an initial asymmetry in the racemic mixtures present on the primordial Earth. This tiny initial asymmetry was probably enough, in the course of chemical and biological evolution, to nudge the system into a highly asymmetric state by one or other of the mechanisms suggested by Wald⁹ and others¹⁰⁻¹².

For the physical interpretation of the effect we rely on the fact¹³ that the symmetry properties of optical isomers are compatible with the existence of second rank pseudotensors characterising the isomers. The correlation tensor $\langle v_\alpha \sigma_\beta \rangle$ between the velocity and the spin of the electrons of the sample is of this type. Therefore those components of the correlation tensor which are allowed by the symmetry may differ from zero. In a solution, for example, the correlation tensor has the form,

$$\langle v_\alpha \sigma_\beta \rangle = K \sigma_{\alpha\beta}$$

where the coefficient K is of different sign in L and D species. In other words, when $K \neq 0$ the electron spins are aligned predominantly parallel to the motion in one of the optical isomers, and antiparallel in the other.

If we suppose that the probability of positronium formation depends on the relative velocity of the positrons and the electrons, then since the positrons are polarised this assumption immediately leads to the consequence that when $K \neq 0$, the relative probabilities of *ortho*- and *para*-positronium formation differ for differential optical isomers. This difference is indeed observed in the experiment described above.

Abnormality in tissue isoferritin distribution in idiopathic haemochromatosis

IDIOPATHIC haemochromatosis (IHC) is generally considered to result from an inherited abnormality of iron metabolism in which excess iron accumulates in tissues such as liver, heart and pancreas, causing structural and functional abnormalities¹. The clinical and pathological features of the disease have been well characterised^{1,2} although the mode of inheritance is uncertain because of the lack of a reliable genetic marker. In spite of several theories³⁻¹¹, the

metabolic abnormality leading to excess iron storage remains unknown.

Much of the excess iron is deposited in ferritin. Although the major function of this protein was thought to be the detoxification and storage of iron, it now seems to have a more extensive function. For example, it acts catalytically in the oxidation and storage of iron^{12,13}, and there is evidence¹⁴⁻¹⁶ for metabolically different ferritins. We found a structural heterogeneity in many tissue ferritins which may correlate with this functional heterogeneity. Most tissues from normal subjects contain several isoferritins, many of which are common to several tissues. The relative distribution and iron content of these isoferritins are characteristic of the tissue of origin (our unpublished results). Because of this evidence of multiple organ-specific forms and metabolically distinct pools of ferritin, and also the demonstration of an alteration in isoferritin profile in human hepatoma¹⁷, we have examined ferritin isolated from liver and other organs in patients with IHC and in control subjects. We found an apparent absence of the more acidic isoferritins that predominate in normal heart, pancreas and kidney ferritin. The haemochromatotic tissue ferritins all closely resembled normal liver ferritin in their isoferritin profile, iron content of the isoferritins and in amino acid composition. By contrast, tissue ferritins isolated from patients with alcoholic cirrhosis or secondary iron overload showed the normal organ distribution in isoferritin profile and in iron content.

Fig. 1 Gel electrophoresis in 4% polyacrylamide using 2% ampholytes, pH range 5-7, of purified ferritin isolated from human liver (L), spleen (S), heart (H), pancreas (P) and kidney (K) from a normal subject (a) and a patient with idiopathic haemochromatosis (b). Between 25 and 35 μ g of protein was applied to all gels. After equilibrium was attained, the gels were stained for protein using Coomassie blue.

Fresh human tissues were obtained post-mortem from three patients with IHC (all untreated and diagnosed according to published criteria¹⁸), two with alcoholic cirrhosis, one with post-transfusional haemosiderosis and two control subjects. Ferritin was isolated by the method of Drysdale and Munro¹⁹ except that carboxymethyl cellulose chromatography was omitted to avoid possible selective loss of isoferritins of differing charge. In contrast to methods which include high speed centrifugation for purification, this procedure ensures the collection of both iron-laden ferritin and the lighter apoferritin, which is important in

Table 1 Amino acid composition of normal and haemochromatosis tissue ferritin

† Includes methionine and methionine sulfoxide.

view of the variable iron content of unfractionated ferritin¹⁹ and its multiple molecular forms (our unpublished results). Each tissue ferritin preparation appeared to be pure by gel electrophoresis since all protein in each preparation also stained for iron with Prussian blue, a commonly accepted criterion for ferritin purity.

The tissue ferritin preparations were also analysed by gel electrofocusing (GEF) at 4° C in 4% polyacrylamide gel cylinders with 2% ampholytes, pH range 5–7, in apparatus from Medical Research Apparatus, Boston^{20,21}. The gels were stained for protein with Coomassie blue or for iron using potassium ferrocyanide. To establish that all protein bands obtained from each ferritin preparation by GEF represented isoferritins and not other contaminating proteins, duplicate gels were subjected to direct immunoprecipitation *in situ* with a specific rabbit anti-human-liver ferritin antiserum. This antiserum recognised all the tissue ferritins with a line of complete identity by Ouchterlony

analysis and, in addition, precipitated all the isoferritins previously demonstrated in the various normal tissues (our unpublished results). The resulting pattern of immunoprecipitates after GEF corresponded in position in each instance to the protein bands (our unpublished results), confirming that all protein bands were ferritins.

In agreement with our previous findings (unpublished), there were characteristic differences in electrophoretic mobilities of the ferritins from normal tissues. These differences were more evident at the higher resolution given by GEF. There were striking differences between the tissue ferritins in the isoferritin distribution and the iron content of the individual isoferritins (Figs 1 and 2). Thus, the number and relative amounts of various isoferritins, as well as their iron content varied with the tissue of origin. This organ-specific variation in isoferritin pattern and iron content was also demonstrable in ferritins isolated from the tissues of the two patients with cirrhosis and one with transfusional haemosiderosis. In contrast, ferritins isolated from each of the five tissues from three patients with IHC were remarkably uniform in electrophoretic mobility, isoferritin profile and the iron content of their isoferritins (Figs 1 and 2). These results were substantiated by amino acid analyses which showed that the composition of different tissue ferritins in IHC were very similar and closely resembled that of normal liver ferritin. This contrasts with the variation in amino acid compositions of normal tissue ferritins (our unpublished results). Immunodiffusion experiments using five animal antisera to heterologous ferritins revealed no immunological differences between normal liver ferritin and the ferritins isolated from haemochromatotic tissues when tested by double diffusion on Ouchterlony plates.

The electrophoretic mobilities and isoferritin profiles of tissue ferritins from a patient with post-transfusional haemosiderosis were normal. Alfrey obtained similar results by electrophoresis with two patients with post-transfusional haemosiderosis²³. Linder-Horowitz *et al.*¹⁶ demonstrated that experimental iron loading in rats did not alter the gene expression for ferritin. It is unlikely, therefore, that the abnormalities in tissue ferritins which we have demonstrated in patients with IHC are merely the result of increased iron concentration. Rather, the atypical isoferritin distribution seems to be specific for this disease.

There is increasing evidence that the structural heterogeneity in different ferritins from normal tissues reflects functional differences in these proteins in iron metabolism^{14,16,23}. Variations in isoferritin profile among normal tissue ferritins may be due either to the presence of different cell populations in the different tissues, or to different metabolic functions of the multiple isoferritins. Recent work²⁴ has suggested that much of the structural heterogeneity in tissue ferritins represents hybrid molecules consisting of different proportions of dissimilar subunits, somewhat analogous to other hybrid isoenzymes such as lactic dehydrogenase. The abnormally uniform distribution of tissue isoferritins which we have demonstrated in IHC could result from the generalised deposition of a catabolic or storage ferritin^{14,15} normally present predominantly in liver and spleen or from a decreased synthesis of the more acidic isoferritins present in heart, kidney and pancreas. This may represent a genetic defect in the synthesis of a subunit type found normally in these tissue ferritins. Whether the abnormality in tissue isoferritins in IHC is directly related to the primary genetic defect of this disease requires confirmation by further studies of asymptomatic relatives of patients and more detailed analysis of the primary structure of ferritin.

This work was supported by a US Public Health Service international postdoctoral research fellowship and grants from the American Cancer Society and the National Institutes of Health.

Fig. 2 Analytical gel electrofocusing was performed as described in Fig. 1. In this case, the gels were stained for iron using Prussian blue. The isoferritins in normal pancreas did not stain for iron, even when the gels were relatively overloaded with protein. *a*, Normal; *b*, haemochromatosis.

A phenylethylamine oxidising defect in migraine

For some two hundred years, certain foodstuffs have been known to trigger migraine attacks¹. In 1967, knowing that cheese is a common dietary trigger to migraine, Hanington² fed tyramine, which it is known to contain, to affected subjects and by this action was able to initiate headache episodes.

Even though cheese and tyramine-containing foods are frequently implicated as headache precipitants, by far the commonest of the dietary triggers is chocolate³ which does not contain tyramine according to a recent analysis performed by the British Food Manufacturing Industries Research Association. This analysis did however reveal the presence of large amounts of phenylethylamine, at least 3 mg per 2 ounce bar; of the other common dietary precipi-

Table 1 Effect of phenylethylamine in chocolate-sensitive migraine

Headache	6	18
No headache	30	18

tants tested, a large number of cheeses, but not all, contained phenylethylamine, as do some red wines (M. J. Saxby, personal communication). It therefore seemed of interest to determine whether oral phenylethylamine alone is able to initiate an attack of migraine in susceptible subjects.

Forty-six migraine sufferers who claimed, in answer to a questionnaire, that their headache attacks were provoked by chocolate, volunteered to take part in the following sighting experiment, which was organised along similar lines to that reported earlier for tyramine².

A capsule containing lactose was sent to each, together with a further questionnaire to be completed and returned 24 h after it had been ingested. Those taking part were asked not to take the capsule within 48 h of a spontaneous migraine attack or when they thought one might be expected. After this questionnaire had been returned, a capsule similar to the earlier one but containing phenylethylamine (3 mg) was sent, together with another questionnaire and similar instructions for its return. Patients were not aware of the contents of either capsule.

Ten subjects failed to complete the trial after lactose ingestion only, which had been followed by headache in five of them. Thirty-six completed the trial, 3 men and 33 women. The results are shown in Table 1. Included in this table are two patients who developed a headache after both lactose and phenylethylamine. One had a mild generalised headache on both occasions but felt sick only after phenylethylamine; the other had a unilateral mild to moderate headache after both. Of the four subjects who had symptoms only after lactose one had no headache at all but saw patterns before her eyes, two had a moderately severe unilateral headache and the fourth a bilateral moderately severe headache.

There seems to be a *prima facie* case for the existence of a cause and effect relationship between phenylethylamine ingestion and migraine headache in certain patients.

One unexplained feature of the phenylethylamine-provoked headaches is that their onset was delayed for approximately 12 h after amine ingestion, a period of the same order as that observed clinically after chocolate

Table 2 Human platelet monoamine oxidase activity

Substrate	Migraine	Patient Control	Chocolate-sensitive migraine
Phenylethylamine	4.38 ± 0.51 (28)	10.66 ± 0.96 (26)	4.16 ± 0.36 (12)
	P < 0.001		P < 0.001
Tyramine	13.52 ± 1.60 (28)	28.48 ± 2.64 (26)	11.80 ± 1.26 (12)
	P < 0.001		P < 0.001
Dopamine	5.61 ± 0.51 (28)	8.29 ± 1.09 (26)	5.04 ± 0.44 (12)
	P < 0.05		P < 0.01
5-Hydroxytryptamine	14.54 ± 1.17 (16)	21.70 ± 1.82 (14)	15.84 ± 1.88 (7)
	P < 0.01		P < 0.05

Each value is expressed as nmol of substrate deaminated per 30 min incubation per mg protein at 37° C. Protein nitrogen was measured according to the method of Lowry *et al.*²⁴ using human serum albumin as standard. Figures in parentheses represent number of subjects.

Fig. 1 Distribution of monoamine oxidase activity in blood platelets from migrainous and control subjects. Activity is expressed as d.p.m. radioactive deaminated metabolites formed per mg protein per 30 min using *a*, phenylethylamine; *b*, tyramine; *c*, dopamine; and *d*, 5-hydroxytryptamine as substrates.

ingestion in susceptible subjects. During the earlier experiment with tyramine² two groups of reactors were observed, with peak onset at 3 h and 12 h respectively. The dose of tyramine used then (100 mg) was considerably larger than that of phenylethylamine (3 mg) in the present trial. A 12 h lag period is puzzling and at first sight, seems to rule out simple trigger action such as that envisaged by one of us¹: taking as his starting point some published observations⁵ in which tryptamine and 5-hydroxytryptamine, when introduced into the afferent pulmonary circulation of an experimental animal, had been shown to cause a release of prostaglandins and other vasoactive agents into the systemic circulation, he suggested that migraine might, in a sense, be a pulmonary disease. A triggering agent arriving at the lungs from the gastrointestinal tract might, as in the perfused animal lung, provoke a secondary release of vasoactive substances to act on the cerebral vasculature. This interpretation has received a measure of experimental support⁶. Recently Y. S. Bakhle (personal communication) has found phenylethylamine to be an effective releaser of vasoactive substances in certain species, rather more so than tyramine⁷.

If Sandler's hypothesis⁴ were valid, one possible explanation to account for a facilitated release of vasoactive substances from the lungs into the systemic circulation would be the access of a higher concentration of monoamine into the afferent pulmonary vessels brought about by defective

inactivation. The predominant inactivation pathway of phenylethylamine involves oxidative deamination by monoamine oxidase (MAO)⁸. There is evidence of decreased platelet MAO activity during headache episodes in migrainous patients^{9,10}.

Johnson¹¹, working with enzymes from rat brain, obtained data which he interpreted in terms of the existence of two types of MAO, termed A and B, and similar conclusions have been drawn from findings on human neural tissue¹². It has been claimed that these forms are immunologically separable¹³. Type A is specific for 5-hydroxytryptamine¹¹ and noradrenaline¹⁴; tyramine¹¹ and dopamine¹⁵ are substrates for both A and B forms. Phenylethylamine is a preferred substrate for MAO B (ref. 16). It therefore seemed to us that, in migraine, we might be dealing with a specific defect of MAO B. To test this hypothesis, a study of platelet MAO activity, using several different substrates, was carried out in a further series of migrainous patients and in non-migrainous controls.

During a headache-free period, venous blood samples from the unselected group of 28 migrainous subjects (9 male, 19 female), age range 20 to 65 yr, were collected into plastic tubes containing lithium heparin. Nonmigrainous volunteers of a similar age range provided control samples. Platelets were collected¹⁷ and stored deep-frozen before assay. MAO activity was measured radiometrically¹⁸ using ¹⁴C-labelled phenylethylamine, tyramine, dopamine and 5-hydroxytryptamine as substrates.

The results are shown in Fig. 1 and Table 2. A highly significant decrease in phenylethylamine oxidising ability was observed in migraine compared with control subjects, but in addition, a difference in tyramine oxidation of a similar order was apparent between the two groups. A smaller but still significant decrease in activity towards dopamine was present. The deficit of MAO A may be less pronounced, for there was a small but significant decrease in 5-hydroxytryptamine-oxidising ability in the migrainous group. In retrospect the decrease in the normally high¹⁷ benzylamine-oxidising ability in platelets from migrainous subjects, observed by another group¹⁹, is compatible with our data on impaired phenylethylamine oxidation, for benzylamine seems to be another substrate of MAO B (ref. 11).

It seems likely, however, that the A and B classification is a gross over-simplification^{19,20}: one of the multiple forms of solubilised MAO which has been isolated electrophoretically²¹ seems to possess, for instance, an extremely high preference for dopamine as substrate. Nevertheless, whichever of the multiple forms of MAO turns out to be implicated in migraine, it seems quite possible that the deficit of phenylethylamine and tyramine-oxidising ability is of functional significance.

The migrainous patients under investigation were a mixed group, some with headache provoked by chocolate or other foodstuff and others without history of dietary precipitant. Platelet samples obtained from patients with dietary compared with non-dietary migraine variants, however, showed no significant difference in their ability to oxidise any of the substrates investigated (Table 2). Before firm conclusions can be drawn from data of this type, more information is needed showing to what extent any platelet MAO defect reflects a similar deficit in small intestinal or perhaps, pulmonary MAO. A pulmonary deficit, for instance, would make larger concentrations of amine available locally, thus helping the threshold to be reached for an 'all-or-none' release²² of vasoactive substances from the lung into the systemic circulation in accordance with Sandler's hypothesis⁴. Were this hypothesis to prove invalid, an alternative and simpler explanation might be that monoamines which escape destruction in the lungs²³ because of an MAO deficit exert some direct action on the cerebral vasculature. Preliminary observation (R. J. Stephens, personal communication), however, indicate that phenylethylamine has little or no direct effect

of this type, at least in the rat.

We thank Margaret Kelly for help in preparing the platelet samples; P. Bradburne for statistical assistance; and the Wellcome Trustees for partial support of this work.

to inhibition of cell multiplication by serum limitation^{4,5}. In addition, different fractions of serum stimulate the growth of untransformed mouse 3T3 fibroblasts and 3T3 cells transformed by SV40 (SV3T3) in culture⁶ which suggests the involvement of different growth promoting molecules for normal and transformed cells. It has been shown that a new pituitary hormone, fibroblast growth factor⁷ (FGF), with a glucocorticoid, hydrocortisone, and with a nonspecific carrier protein could completely replace exogenously added serum for the induction of the complete mitogenic response in lines of BALB/c 3T3 cells⁷, whereas virtually no effects were observed on virally transformed cells (P. S. R., W. S. and D. G.; manuscript in preparation). In the presence of serum exhausted for its growth-initiating ability only FGF was required to initiate or increase DNA

BALB/c 3T3 cells¹³, polyoma transformed BALB/c cells (Py3T3), and temperature-sensitive transformed BALB/c 3T3 cells (ts 3T3 Cl.1) were plated at 10⁵ per 5 cm Petri dish and grown in Dulbecco's Modified Eagles Medium (5 ml) in 2% calf serum (Colorado) at 32° or 39° in a 10% CO₂ atmosphere. The CO₂ pressure was slightly varied to maintain a constant pH in the medium at the two temperatures. After 2 or 3 d when the final cell density was about 3 × 10⁵ per plate (3T3: 3.0 and 3.1; ts 3T3: 2.9, 3.0; and Py3T3: 1.6 and 4.5 × 10⁵ cells at 39°C or 32°C respectively) 50 ng ml⁻¹ of FGF or 10% serum (6 mg ml⁻¹) were added to the growing cultures. Autoradiography of control dishes without additions showed that more than 70% of all cell nuclei became radioactively labelled during the first 12 h after the time of addition of ³H-thymidine. Cultures were radioactively labelled with 3 µCi ml⁻¹ ³H-methyl thymidine at 3 µM from 7 until 30 h after additions, or the cells were counted in a Coulter Counter 48 h afterwards. The c.p.m. of ³H-thymidine incorporated into DNA (ref. 16) per 10 cells (a) or the number of cells per 5 cm Petri dish × 10⁻⁵ were recorded (b). FGF, a homogeneous polypeptide of molecular weight 13,400 was purified from bovine pituitary glands as described previously⁷.

synthesis and cell division; the hydrocortisone concentration present in serum was considered to be sufficiently high not to require further addition⁷. We have now investigated the ability of FGF to promote the growth of cell mutants of BALB/c 3T3 which show temperature dependent changes in many properties characteristic of the transformed state (W. E., manuscript in preparation). We found that FGF initiates DNA synthesis and cell multiplication only at the non-permissive temperatures ('normal' state) but fails to initiate or promote cell growth at permissive temperatures (transformed state).

Cell mutants with temperature-sensitive (ts) lesions in many properties characteristic of transformed cells have been described for SV3T3⁸ and baby hamster kidney⁹ (BHK) cells, similar to the earlier reports of temperature sensitive variants of BHK obtained by transformation with a thermosensitive mutant of polyoma virus¹⁰. Recently Eckhart has selected several different clones of BALB/c 3T3 cells which show temperature dependent properties. Properties of the three mutant clones used in this paper are stable and can be summarised. Cells from these clones show transformed morphology and ability to grow in agar at 32° C but normal morphology and lack of growth in agar at 39° C (W. E., unpublished observations). Growth rates are 1.8, 2.0 and 1.7 times as fast at 32° C as at 39° C in medium containing 10% serum. Their final cell densities in medium containing low serum concentrations are approximately 10 to 3-fold higher at 32° C than at 39° C (for example for ts 3T3 clone 1 in 0.25%, 0.5% or 2% serum

Cell transformation mutants are not susceptible to growth activation by fibroblast growth factor at permissive temperatures

CHEMICAL¹ or viral² transformation of fibroblasts in tissue culture results in cell variants with different properties from the original cells (see ref. 2 for review). These properties include morphological changes, surface alterations³ and an increased growth ability under various conditions. This changed pattern in growth control of many transformed cells is manifested *in vitro* by their ability to grow in agar, to attain higher saturation densities in monolayer cultures and to be much less responsive

Table 2 Stimulation of DNA synthesis in different cells

FGF	85.6	64.5	42.5	56.8	59.2

Abbreviations: 3T3; BALB/c 3T3; ts Cl.1, Cl.10, Cl.X: temperature sensitive transformed BALB/c 3T3 cell-lines; Py3T3: polyoma transformed BALB/c 3T3. The percentage of ^3H -thymidine incorporated into DNA compared with serum addition is shown. Cells were grown in DEM and 10% serum as described (Table 1) at either 32° C or 39° C until confluent (10^6 cells per 5 cm plate). Medium was then removed, cell monolayers were washed twice with DEM containing $250 \mu\text{g ml}^{-1}$ bovine serum albumin (BSA) and fresh DEM containing 0.2 ng ml^{-1} FGF, $0.5 \mu\text{g ml}^{-1}$ hydrocortisone (cortisol, Calbiochem) and $250 \mu\text{g ml}^{-1}$ BSA. After 3 d 50 ng ml^{-1} of FGF or 10% serum (6 mg ml^{-1}) was added and the cultures were radioactively labelled with ^3H -thymidine from 8 until 34 h after additions, the c.p.m. of ^3H -thymidine incorporated into DNA was recorded. Results for no addition or the addition of FGF are expressed as the percentage of the c.p.m. incorporated into DNA in the presence of 10% serum. Autoradiography of parallel cultures showed that the percentage of radioactivity labelled nuclei in the population with FGF addition were: for 3T3, 95 and 90; for ts 3T3 Cl.1, 1 and 60; for Cl.10, 10 and 40; for Cl.X, 7 and 51; for Py3T3, 40 and 53 at 32° C and 39° C respectively. Without addition of 50 ng ml^{-1} FGF the percentage of radioactively labelled nuclei was less than 1% for 3T3, ts 3T3 Cl.1 at 32° C and 39° C, Cl.10 and Cl.X at 39° C while for the remainder: Cl.10, 7%; Cl.X, 4% at 32° C; Py3T3, 41% at 32° C and 60% at 39° C. The percentages of the cell population which had divided by 48 h after addition of 50 ng ml^{-1} of FGF were for 3T3, 96 and 86; for Cl.1, 4 and 82; for Cl.10, 16 and 87; for Cl.X, 9 and 88; for Py3T3, 50 and 54 at 32° C and 39° C respectively.

the final cell densities were 19 and 2.2, 20 and 3, 32 and 11×10^6 cells per 5 cm dish at 32° C and 39° C respectively). At low serum concentrations (Table 2), ts 3T3 Cl.1 and to a lesser extent Cl.10 and Cl.X can be made to exhibit density-dependent inhibition of growth at 32° C similar to nontransformed 3T3 cells and unlike the virally transformed lines Py3T3 and SV3T3⁵. After addition of 20% serum to such quiescent cultures at 32° C they synchronously initiate DNA synthesis followed by cell division at times compatible with an original cell population arrested in the G_0 phase of the cell cycle (unpublished results).

Addition of FGF to cultures of BALB/c 3T3 growing slowly with 2% serum in the medium increased both rates of DNA synthesis and cell division but failed to increase growth rates of polyoma transformed 3T3 cells (Py3T3) (Table 1). For ts-3T3 clone 1 (ts-Cl.1) cells addition of FGF specifically increased cellular growth rates at 39° C but not at 32° C. 10% serum addition markedly increased DNA synthesis and cell division in all cultures (Table 1). The ability of FGF to initiate DNA synthesis in quiescent cultures was also checked. It was however impossible to maintain resting cultures of BALB/c 3T3 cells with Dulbecco's modified Eagle's medium (DEM) and only BSA, and hence low concentrations of FGF (0.2 ng ml^{-1}) and hydrocortisone were added to prevent cell deterioration¹¹. Addition of saturating amounts of FGF (50 ng ml^{-1}) to quiescent cultures of 3T3, ts Cl.1, Cl.10, Cl.X at 39° C induced a 40- to 80-fold increase in DNA synthesis but virtually no increase in resting cultures of ts Cl.1 at 32° C. It was more difficult to obtain completely quiescent cultures of ts Cl.10 and Cl.X at 32°, but FGF failed to increase the small residual amount of DNA synthesis (Table 2). Py3T3 cells continued synthesising DNA at half the rates of those in 10% serum but no additional stimulation was observed upon FGF addition (Table 2). Approximately twice the amount of FGF was added to the cultures in Tables 1 and 2 than was required for complete induction of DNA synthesis and cell division in resting cultures of BALB/c 3T3 cells (manuscript in preparation). Further increased additions of FGF up to five times the amounts added in Table 2 failed to stimulate DNA synthesis in mutant cultures maintained at 32° C,

whereas 10% serum addition induced more than 95% of the cells to synthesise DNA and divide.

The ability of various hormones to promote the initiation of DNA synthesis in resting cultures of ts Cl.1 at either 32° C or 39° C is shown in Table 3. Insulin at high, nonphysiological concentrations was reported to induce DNA synthesis and cell division in fibroblasts maintained in the presence of serum^{13,14}. But in the absence of serum, insulin at physiological (Table 3) (10^{-9} to 10^{-8} M) or nonphysiological (10^{-6} M) (unpublished results) concentrations failed to induce DNA synthesis in more than 5% of the cell populations at either temperature. FGF without hydrocortisone still induced DNA synthesis in a significant fraction (22%) of the mutant cells at 39° C but not at 32° C. With hydrocortisone the induction of DNA synthesis was comparable to that with serum at 39° C while only serum induces DNA synthesis at 32° C.

A comparative biochemical study of normal and transformed cells in tissue culture is complicated by the fact that often two very different cell types are being compared (for example,

Table 3 Induction of DNA synthesis by different hormones

Additions	^3H -DNA (c.p.m. $\times 10^{-6}$)		Labelled nuclei (%)	
	32° C	39° C	32° C	39° C
none	0.5	0.2	1.8	1.0
HC	0.7	0.2	2.6	1.2
FGF	0.7	5.8	2.8	22.7
insulin	0.4	0.8	2.1	3.0
HC + FGF	0.4	10.8	3.1	66.2
HC + insulin	0.3	0.3	2.0	1.6
HC + FGF + insulin	0.7	9.9	3.2	67.2
serum	12.0	11.5	92.5	71.7

Cell cultures of the temperature sensitive transformed BALB/c 3T3, clone 1 were plated and grown as described in Table 2. At confluency (10^6 cells per 5 cm dish) the medium was removed and the cell monolayers washed twice as described. Medium containing 0.2 ng ml^{-1} FGF and $250 \mu\text{g ml}^{-1}$ BSA was added back and the cultures incubated at their respective temperatures for another 3 d. To the resting cultures either $0.5 \mu\text{g ml}^{-1}$ of hydrocortisone (HC), 50 ng ml^{-1} fibroblast growth factor (FGF), 50 ng ml^{-1} insulin (bovine pancreas, Calbiochem) or 10% serum was added as indicated. Cultures were radioactively labelled with either $3 \mu\text{Ci ml}^{-1}$ ^3H -thymidine at $3 \mu\text{M}$ for DNA synthesis or at $1 \mu\text{M}$ for autoradiography, from 10 until 34 h after additions. The c.p.m. of ^3H -thymidine incorporated into DNA $\pm 10^{-6}$ per culture or the fraction of cells with radioactively labelled nuclei is shown for various hormone additions. Cell numbers were 9.2 and 9.3×10^6 cells per 5 cm dish at 32° C and 39° C respectively before the additions, and FGF + HC addition increased cell numbers to 9.4 and 17.0×10^6 at 32° C and 39° C respectively measured after 48 h.

chromosomal differences in SV3T3 and 3T3), and the observed differences could arise as a result of the transformation event itself or as a consequence of the selection for a particular stable transformant. With cells possessing thermosensitive lesions in the expression of the transformed phenotype, however, the latter difficulty is obviated. We now show that the growth-initiating properties of a mutant 3T3 cell can be controlled by a single purified polypeptide hormone at the nonpermissive temperature; this ability is lost at the permissive temperature when the cells exhibit many of the properties characteristic of the transformed state. Other components in serum can control the growth at this permissive temperature. The cellular site of action of many of the polypeptide hormones is the adenyl cyclase in the plasma membrane¹⁴. We have previously shown that FGF can directly activate the membrane-bound guanyl cyclase in 3T3 but not in SV3T3 cells (manuscript in preparation). This suggests that the temperature-sensitive lesion in the mutant cells is either wholly or in part caused by a membrane change. This change possibly prevents the polypeptide hormone from elevating intracellular cGMP concentrations to a level which may be responsible for the initiation of cell growth¹¹.

We thank Dr R. Dulbecco for support and encouragement, Drs R. Dulbecco, R. Bürk, and M. Shodell for criticisms of the

manuscript and Margaret Seeley for technical assistance. This work was supported by a Helen Hay Whitney Fellowship to P. S. R. and by National Institutes of Health grants to D. G. and Dr R. Dulbecco.

Manipulation of sexual physiology by brain stimulation in insects

In insects the pars intercerebralis (PI) is a median protocerebral neurosecretory centre associated with postcerebral neurohaemal organs, the corpora cardiaca (CC). Numerous investigations based on ablations or implantations of the PI and CC have shown that the neurohormones released by the CC intervene in many physiological processes. *In vitro*, by means of electrical stimulations, it was possible to show that, as in vertebrates, there is a coupling between depolarisation and secretion¹. One may therefore contemplate the development of a new technique of investigation in neuro-endocrinology by electrical stimulation *in vivo* of neurosecretory cells. We were able to provoke by this way a precocious ovarian development in female locusts.

Experiments involving ablation and implantation showed that oocyte maturation and egg laying are under the endocrine control of the PI^{2–5} and a pair of endocrine glands, the corpora allata (CA)⁶. We tested two different situations by using the females of a species (*Locusta migratoria*) in which the oocytes develop immediately after metamorphosis (the first batch of eggs is laid after about 18 d) and the females of a species (*Anacridium aegyptium*) subject to an ovarian diapause of 6 months. The opening of a dorsal tegumentary cephalic window enables access to the PI which is superficial. The stimulatory electrode used is a stainless steel wire 30 μ m in diameter, insulated in an epoxy resin. Rectangular pulses of 30 μ A and 1 ms are applied at 5 s⁻¹ for 10 min between the stimulatory electrode

Fig. 1 Mean length (mm) of the first generation of oocytes in *Locusta*, on day 10 of imaginal life, after various electrical stimulations. *a*, Controls (electrode placed in the PI without passage of current; 16 animals, 1 died); *b*, stimulation of the ventral nerve cord; (16 animals, 2 died); *c*, stimulation of the deutocerebrum (16 animals, none died); *d*, stimulation of the PI (17 animals, 2 died, 2 laid one batch of eggs).

introduced into the PI and a thoracic indifferent electrode. After stimulation, the dorsal fin tegumentary window is closed. It is thus possible to achieve a stimulation every 48 h; each individual was subject to two stimulations (*Locusta*) or three (*Anacridium*). The results were compared with those obtained in the controls subjected to the introduction of an electrode without passage of current, the stimulation of the first abdominal ganglion, and stimulations of various regions of the brain (deutocerebrum in *Locusta*, tritocerebrum in *Anacridium*). The conditions were the same as for the operated animals. A parallel histological study enables verification of the placement of the electrode and the emptying of the cell bodies of the PI after stimulation. The results were expressed in terms of the length of the first oocyte generation 8 d (*Locusta*) (Fig. 1) or 28 d after the first stimulation (*Anacridium*) (Fig. 2).

In *Locusta*, stimulation of the PI is accompanied by a rapid growth of the oocytes. The first generation oocytes on day 10 have an average length of more than 6 mm (Fig. 1d); in all the controls (Fig. 1a, b and c), this length remains below 2 mm. This rapid growth even induced 2 of the 15 stimulated animals to lay eggs before day 10; in the usual breeding conditions egg laying occurs only about day 18.

In the case of *Anacridium*, the adult females used were about 2 month old and in natural conditions would have laid eggs only 6 months later. The triple stimulation of the PI provoked a partial emptying of the cell bodies of the PI and rupture of the ovarian diapause. All the animals laid eggs at least once in the 28 d following the first stimulation; one of them even laid twice. The first oocyte generation at this time had an average length close to 7 mm, so the eggs were mature (Fig. 2d). In all the controls (Fig. 2a, b and c) the average length of this same generation is less than 2 mm and storage of the protocerebral neurosecretion was observed^{4,5}.

Finally, it is possible to associate the stimulation method with that of ablations. Thus, in the case of *Anacridium*, stimulation of the PI of allatectomised animals results in almost zero growth of the oocytes (Fig. 2e): the gonadotrophic role of the CA is thus confirmed. Conversely, ani-

Fig. 2 Mean length (mm) of the first generation of oocytes in *Anacridium* 28 days after various electrical stimulations. *a*, Controls (electrode placed in the PI without passage of current; 14 animals, none died); *b*, stimulation of the ventral nerve cord (14 animals, 2 died); *c*, stimulation of the tritocerebrum (15 animals, 1 died); *d*, stimulation of the PI (13 animals, 2 died, all the survivors laid one batch of eggs, one animal laid two batches); *e*, stimulation of the PI after allatectomy (14 animals, 4 died); *f*, stimulation of the PI after section of the allatocardiac nerves (14 animals, 5 died, 8 animals laid one batch of eggs and 1 contained chorionated eggs ready to be laid).

imals in which the CA have been disconnected (by section of the allatocardiac nerves) experience, after stimulation of the PI, the same growth of the oocytes as that observed in animals in which the CA were not disconnected (Fig. 2*d* and *f*). The mode of action of the PI on the CA is therefore established as humoral rather than nervous.

Our results show unequivocally that the method used provokes a certain release of protocerebral neurosecretion followed by intense activation of oocyte maturation. In the case of *Locusta*, one may thus obtain precocious maturation and in the case of *Anacridium* rupture of the ovarian diapause. This method seems to be more efficacious—at least in the case studied—than the classic techniques of implantation. In effect, to obtain a simple maturation of the ovaries, in *Anacridium*, it is necessary to implant four active PI or four active CA³.

Certain general nonspecific stimulations, such as forced activity of the animals or the electrical stimulation of various regions of the brain, may provoke the start of a histologically detectable emptying of the cells of the PI and a very slight development of the oocytes². There is no doubt that the results obtained here are due to a specific stimulation of the PI and not to a general activation: the stimulation of a wide variety of regions of the central nervous system never provoked any maturation of the oocytes.

We thank Paula Harry for preparing the English manuscript.

Properties of a calcium channel in snail neurones

In most cases where the action potential of nerve cells has been studied the initial inward current has been found to be carried by sodium ions. More recently calcium has been shown to be an important charge carrier in the inward current of vertebrate cardiac muscle, vertebrate smooth muscle and many nerve cell bodies¹. It is therefore of interest to know whether the properties of the calcium conductance mechanism are similar to those which have been described for sodium conductance. An important property of the sodium conductance mechanism is its reduction or 'inactivation' by a conditioning depolarisation prior to an action potential and its increase by conditioning hyperpolarisation.

This activation and inactivation property can be studied in voltage clamp experiments. The membrane potential is displaced from the holding potential (V) to a conditioning potential (V_c) and then to a fixed test potential (V_t) (see Fig. 2). The inward current (I_t) during the test potential is measured and I_t relative to the maximum inward current obtainable with that test pulse (I_t/I_{max}) is plotted against conditioning potential V_c . In squid giant axon Hodgkin and Huxley² showed that this inactivation behaviour was described by the expression:

$$I_t/I_{max} = [1 + \exp(V_h - V_c)/k_h]^{-1} \quad (1)$$

where V_h is the potential at which $I_t/I_{max} = 0.5$ k_h is a shape parameter.

In the *Aplysia* giant neurone Geduldig and Gruener³ found that in Ca-free saline containing Na the relationship between inward current and conditioning potential was similar to that in squid giant axon. In Na-free saline containing Ca ions, however, a hyperpolarising conditioning pulse reduced the inward current. Geduldig and Gruener³ have suggested that there is a fundamental difference between the activation mechanisms for Na and Ca ions in *Aplysia*. In *Helix pomatia* Neher⁴ found a similar reduction of inward current following a hyperpolarising conditioning pulse in normal saline containing both Na and Ca ions but proposed that it was due to activation of a fast transient outward potassium current which subtracted from the inward current. The experiments described here on *Helix aspersa* neurones suggest that the apparent hyperpolarising inactivation of Ca conductance is due to an early outward current which is sensitive to tetraethylammonium (TEA) and calcium ions.

The neurone used in each experiment was identified as Cell A⁵. This cell lies in the right parietal ganglion and shows an inward current in both Ca-free and Na-free salines in voltage clamp experiments. The cell was impaled with two 3 M KCl-filled microelectrodes of resistance 4–6 MΩ and 0.8–1.3 MΩ respectively. A voltage clamp circuit similar to that of Geduldig and Gruener³ was used, giving a voltage rise time of about 100 μs. Normal saline contained NaCl 75 mM, KCl 5 mM, MgCl₂ 15 mM, CaCl₂ 10 mM, Tris-Cl 5 mM, buffered to pH 7.5. In Na-free saline NaCl was replaced by 83mM Tris-Cl. In Ca-free saline CaCl₂ was replaced by MgCl₂. In (Na, Ca)-free saline both substitutions were performed.

In an attempt to eliminate the effect of early outward currents a current-separation procedure was used as follows. A clamping run consisting of a series of different conditioning potentials each followed by the same test potential was performed in the test solution (either Na-free or Ca-free saline). An identical run was then performed in (Na, Ca)-free saline, in which there is no inward current. (There may be an outward current carried by Na and Ca ions but because of their low intracellular concentrations this was small at the test potential used). The current in (Na, Ca)-free saline at a particular time after the beginning of the test pulse was then subtracted from that in the test solution to give the Na or Ca inward current alone. (All runs were interspersed with controls in normal saline.)

Figure 1a shows the results of such an experiment using Ca-free saline as the test solution. I_i/I_o is plotted against the potential of the conditioning pulse. I_o is the inward current with no conditioning pulse and is used instead of I_{max} as the cell is maximally activated at the holding potential. The conditioning potential was 300 ms long which was found to be long enough for maximum effect. The solid line is drawn to equation (1) with $V_h = -27$ mV and $k_h = -4$ (for squid $k_h = -7$). Thus the inactivation curve for sodium current is adequately described by the same equation as used for squid giant axon.

Figure 1b shows a similar experiment in Na-free saline (in which the inward current is carried by Ca ions). The solid line

Fig. 1 *a*, Inactivation curve in Ca-free (Na-containing) saline. Ordinate: peak inward current relative to peak inward current with no conditioning pulse (I_i/I_o). Conditioning pulse length 300 ms. Holding potential (V) (arrowed) = -48 mV. Test pulse potential (V_e) = $+14$ mV. Cell 104. Diameter $180\text{ }\mu\text{m}$ 22.5°C . Solid line drawn to equation (1) with $V_h = -27$ mV; $k_h = -4$. *b*, Inactivation curve in Na-free (Ca-containing) saline. Conditioning pulse length 500 ms. $V_e = +10$ mV. Cell 139. Diameter $230\text{ }\mu\text{m}$ 20°C . Solid line drawn to equation (1) with $V_h = -24$ mV; $k_h = -4$.

is again drawn to equation (1). For depolarising conditioning pulses a good fit is obtained. But with increasing hyperpolarising pulses I_i/I_o falls steeply and then rises more slowly towards unity. Thus there is a considerable deviation from the behaviour described by equation (1). If these results arise from a property of the inactivation system for Ca conductance then this system must be both different from, and more complicated than, that for sodium conductance in *Helix* and squid giant axon. An alternative explanation is that the deviation may arise from the effect of an early outward current which was not eliminated by the current separation procedure. An early outward current activated by hyperpolarising conditioning pulses exists in many molluscs including *Aplysia*, *Helix pomatia* and *Helix aspersa*^{4,6}. If this early outward current was smaller in the (Na, Ca)-free saline than it was in the Na-free saline

Fig. 2 Voltage clamp records showing effect of TEA. Upper traces voltage, lower traces current. Inward current is shown by a downward deflection. Holding Potential (V) = -48 mV; $V_e = +12$ mV. *a*, no prepulse in Na-free saline; *b*, 500 ms prepulse to -108 mV in Na-free saline (arrow shows early outward current); *c*, no prepulse Na-free saline with 50 mM TEA Cl; *d*, 500 ms prepulse to -108 mV Na-free saline with 50 mM TEA Cl. Cell 168. Diameter $205\text{ }\mu\text{m}$ 19°C .

then the amount of outward current subtracted would be too small. This could be, for example, if the early outward current was to some extent Ca-sensitive. There are two ways in which the absence of Ca in the external saline could affect the size of the early outward current. (1) The change in Ca concentration could shift the activation curve of the early outward current along the voltage axis as found for Na and K conductance in squid⁷. (2) The late outward potassium current in *H. aspersa* has a Ca dependent component so it is possible that the early outward current has a similar component⁸.

In order to test whether this deviation from equation (1) did indeed arise from a Ca-sensitive early outward potassium current the effect of 50 mM TEA was tested. This was a sufficient concentration to reduce late K currents. Figure 2 shows current records obtained under voltage clamp in Na-free saline with and without TEA. It can be seen that TEA reduces the late K current and also the early outward current seen with a hyperpolarising prepulse, but does not affect the Ca inward current. Figure 3 shows the effect of TEA on the dip in the inactivation curve in Na-free saline. Open circles are points obtained by subtraction of currents recorded in (Na, Ca)-free saline from currents in Na-free saline—that is, a similar experiment to that shown in Fig. 1b. Open triangles are results in which the same subtraction was performed when both salines contained 50 mM TEA-Cl substituted for Tris-Cl. The deviation from equation (1) is greatly reduced and in one experiment was abolished altogether. The TEA has no effect

Fig. 3 Effect of TEA on inactivation curve in Na-free saline. \circ , Without TEA; \triangle , with 50 mM TEA Cl; V (arrowed) = -45 mV; $V_e = +15$ mV. Cell 178. $180\text{ }\mu\text{m}$ 21°C . Solid line drawn to equation (1) with $V_h = -23$ mV; $k_h = -4$.

on the normal inactivation by depolarising conditioning pulses.

From the results of these TEA experiments it seems likely that the deviation of Ca inactivation from equation (1) is due as Neher suggested to an early outward potassium current. The current subtraction method of compensating for this current is inadequate, probably because the current is sensitive to calcium. This cannot be shown directly but when K currents are reduced using TEA the deviation from equation (1) is also reduced or abolished. It has recently been shown that hyperpolarising inactivation of Ca current in guinea pig smooth muscle can be blocked by TEA ions⁹. The deviation is also abolished by large hyperpolarising conditioning pulses to potentials more negative than -90 mV probably because the early outward potassium current shifts in time relative to the inward Ca current with increasing prepulse potential.

Thus, it appears that the inactivation behaviour of Ca-conductance in *H. aspersa* is similar to that of the Na-conductance and can be described adequately by equation (1). It is unclear in *H. aspersa* whether the Na and Ca ions pass through the same channel or separate channels. But in vertebrate heart muscle the Ca inward current can be obtained relatively free from other currents in normal saline and does not show hyperpolarising inactivation¹.

I thank Dr R. W. Meech for advice and criticism and the Science Research Council for a studentship.

Resistance of mitotic B lymphocytes to cytotoxic effects of anti-Ig serum

THE use of antisera with specificity for cell surface antigens of T and B lymphocytes has become an increasingly important tool in cellular immunology, being extensively used both preparatively, and analytically^{1,2}. Very little is known, however, about the possibilities of variation in antibody-induced cytotoxicity during the various stages of the cell cycle of normal T and B lymphocytes. Studies mostly examining histocompatibility or virus-associated antigens on synchronised cell cultures of various tumour cell lines have yielded conflicting findings; in some cases cells seem to be most sensitive to antibody and complement during mitosis and perhaps early G₁³⁻⁵, whereas in others, the target cells have been judged to be insensitive in all phases except G₁^{6,7}.

If, depending on the nature of the lymphocyte and cell surface antigen, there is a similar variation to antibody-induced cytotoxicity during different phases of the cell cycle, this could have clear practical and theoretical implications. In particular, antisera are sometimes used to eliminate or assess cells in antigen-activated lymphoid cell populations which may contain a significant proportion of specifically activated cells, in various stages of the cell cycle, including mitosis. In this communication we

present evidence to show that although mouse B lymphocytes are uniformly killed by a heterologous anti-mouse immunoglobulin serum (anti-Ig) in the presence of complement, B cells in mitosis are resistant to such treatment.

Heterologous anti-Ig sera are being used with increasing frequency to kill B lymphocytes (see for example, refs 8-11); since B cells, in contrast to T cells, contain a dense coat of cell surface Ig (ref. 12), the cytotoxicity of anti-Ig can be selective for B cells after appropriate absorption. The preparation and cytotoxic properties of the anti-Ig used in these experiments is described in Table 1. In agreement with the other results^{9,10}, treatment of spleen cells with the anti-Ig, after it had been absorbed with thymocytes,

Table 1 Cytotoxic effects of rabbit anti-mouse Ig serum plus complement on mouse lymphocytes

Spleen§	12

The rabbit anti-mouse Ig serum used in these experiments was prepared as follows: 50 ml of neat serum from a large number of CBA mouse donors was precipitated in saturated ammonium sulphate to isolate gamma globulins²⁶. The precipitate was dissolved in saline and the process repeated twice. The final precipitate was dissolved in 4 ml of saline. Two millilitres of this was mixed with 2 ml of Freund's complete adjuvant (Burroughs Wellcome) and injected intramuscularly into a New Zealand White rabbit. The rabbit was boosted 2 and 4 week later with an intravenous injection of 1 ml of the saline solution containing the dissolved mouse γ globulins. Two weeks later the rabbit was bled, the serum collected and frozen at -20° C in 0.5 ml aliquots. The antiserum was first heat inactivated at 56° C for 30 min. Before use it was absorbed with CBA mouse thymocytes by incubating three volumes of antiserum with one volume of packed washed thymocytes for 60 min at 0° C with shaking every 5 min. The antiserum was tested for cytotoxicity using a two stage microcytotoxicity system¹⁰, in which the first stage was carried out at 0° C so as to prevent capping of cell surface Ig by the anti-Ig¹³. Centrifugations were carried in the cold. Assessment of dead cells was calculated by trypan blue exclusion testing. Normal rabbit serum was used as a control and the results expressed as a cytotoxic index, that is:

$$\frac{\% \text{ dead cells (anti-Ig)} - \% \text{ dead cells (NRS)}}{\% \text{ dead cells (NRS)} \times 10^{-2}}$$

*Anti-Ig not absorbed with thymocytes in this case.

†Cells obtained from adult thymectomised, lethally irradiated, bonemarrow reconstituted mice, 2 months after reconstitution.

‡Anti-Ig absorbed with mouse γ globulins (M γ G) as well as thymocytes. Neat anti-Ig (0.5 ml) was mixed with 0.5 ml of Sepharose beads coated with M γ G by cyanogen bromide activation. The incubation was carried out at 0° C for 1 h. Anti-Ig not absorbed with M γ G and diluted 1:4 as a control gave over 40% kill in this experiment.

§The primary stage of the assay was carried out at 37° C.

inhibited the *in vitro* response to *Escherichia coli* LPS but spared the PHA response (M. J. D. and R. S. K., unpublished observations). The % of cells killed from the various tissue sources is very close to the known corresponding percentage of B cells as assessed by other methods². If the primary stage of the assay was carried out at 37° C instead of 0° C, cytotoxicity was greatly diminished as found by Takahashi *et al.*¹³ which is presumably due to polarisation and loss of cell surface Ig induced by the anti-Ig ('capping') which occurs at 37° but not at 0° C (ref. 14). Absorption of the antiserum with mouse γ -globulin also markedly reduced the cytotoxic activity of the anti-Ig. Before thymus cell absorption, the anti-Ig killed almost all nucleated cells in the spleen and thymus, but after absorption, it was

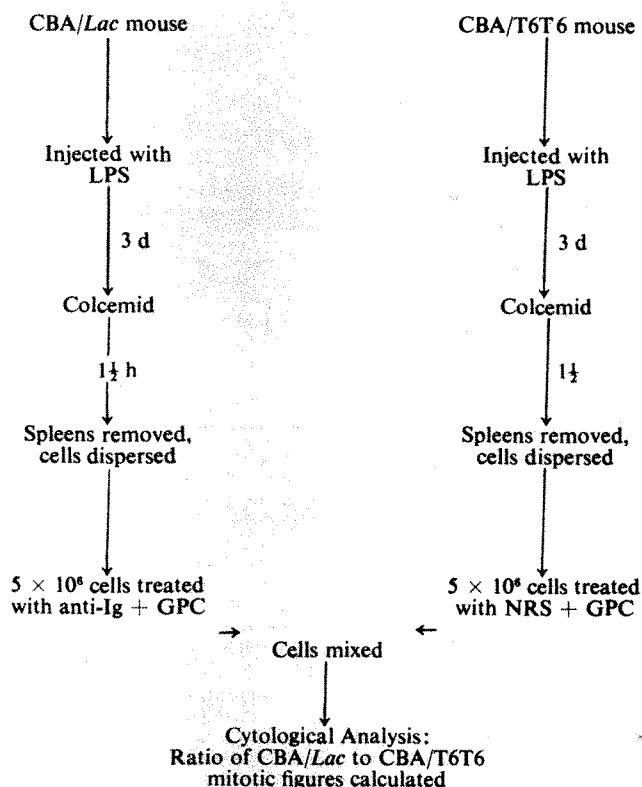

Fig. 1 The assay system¹⁶ used to treat and evaluate the effects of antisera (in this case, anti-Ig) plus GPC on mitotic B lymphocytes. Mitotic T cells are induced by stimulation with oxazolone and removing draining lymph nodes 3 d later¹⁶. Not shown above is the control in which both CBA/Lac and CBA/T6T6 cells are treated with NRS + GPC prior to mixture and cytological analysis. Since the cells are mixed in equal numbers, the ratio of mitotic figures should be roughly 50:50. The effect of the antiserum treatment on the CBA/Lac to CBA/T6T6 mitotic figures in the two different mixtures¹⁶. The percentage of mitotic cells killed was calculated by a cytotoxic index in which the ratio of CBA/Lac to CBA/T6T6 in the antiserum treated mixture is subtracted from the NRS-treated mixture and divided by the latter ratio. The figure is then multiplied by 100. CBA/Lac can be distinguished from CBA/T6T6 mitotic figures by virtue of the fact that the latter contain a tiny pair of marker chromosomes which can be easily visualised when the cells are arrested in metaphase¹⁷. The LPS used was *E. coli* 0:55 LPS (Difco) and the colcemid was purchased from Ciba Labs Ltd. (Horsham, Sussex).

devoid of cytotoxic activity when tested against thymocytes, though still able to kill almost 50% of spleen cells.

The anti-Ig was then examined for its ability to kill B lymphocytes arrested in mitosis. In addition, other antisera were tested such as anti- θ (ref. 1), anti-H2 and anti-MBLA¹⁵. The assay system used has been described in detail¹⁶; it uses chromosome marker techniques¹⁷ and is outlined diagrammatically in Fig. 1.

In Table 2 are recorded the results of experiments in which several types of antisera were tested for their ability to inhibit oxazolone-induced mitotic T cells¹⁶, or LPS-induced mitotic B cells. Anti- θ eliminated 100% of mitotic cells found in the draining lymph nodes of oxazolone-stimulated mice, as did anti-H2 serum. Conversely both anti-MBLA (a marker for B cells¹⁵) and anti-Ig were without such an effect. When LPS-induced mitotic cells were treated, anti-H2 and anti-MBLA were both found to be highly cytotoxic, whereas anti- θ was totally devoid of any such activity. But the anti-Ig was also found incapable of killing these LPS-induced mitotic cells in spite of the fact that 47% of the LPS-immune spleen cells could be killed in the same suspension as assessed by trypan blue cytotoxic testing.

In a parallel experiment, *E. coli* LPS was used as a mitogen to activate spleen B cells *in vitro*¹⁸ and PHA (Burroughs

Wellcome) was used to activate T cells¹⁹ in separate control cultures using methods described previously²⁰. Again anti-Ig was found to possess little ability to eliminate mitotic cells activated *in vitro* by LPS, whereas anti- θ eliminated about 90% of PHA-activated mitotic cells (Table 3).

It may be that the cell surface Ig molecules associated with B cells undergo a density or possibly distributional change²¹ during mitosis such that the cells are no longer capable of being lysed by anti-Ig and GPC. Antigen density on cells is known to play a critical role in complement-mediated cytolytic reactions²² as well as antigen distribution²¹. Buell and Fahey²³ tested Ig-bearing and Ig-producing human lymphoid culture cell lines during different phases of the cell cycle for the presence of Ig by direct immunofluorescence techniques. They found little Ig apparent immediately before, during, and immediately after mitosis; in contrast the G₁ and S phases were highly positive²³. Similar results were obtained by Takahashi *et al.*²⁴.

A factor which should not be overlooked in these experiments is the possible effect of colcemid itself on cell surface Ig: mitotic inhibitors such as colcemid are known to have an effect on lymphocyte receptor mobility²⁵. It should, however, be stressed that anti-Ig + GPC still killed almost 50% of spleen cells from LPS-injected mice which had been given colcemid *in vivo*, and where the assay was carried out in the presence of colcemid (Table 2).

We have also found that treatment of LPS-immune, colcemid treated spleen cells with rabbit anti-Ig followed by a sheep anti-rabbit immunoglobulin serum in the presence of complement was still incapable of killing cells arrested in mitosis (Table 3) (R. S. K., unpublished observations), which suggests that there may be loss of cell surface Ig on the mitotic cells. We are presently studying the cell surface Ig on mitotic B cells using peroxidase staining and electron microscopic

These results indicate that treatment of antigen-activated lymphoid cell populations with anti-Ig plus complement to kill B cells (for example, ref. 11) may spare a small number of specifically activated cells which could partially

Table 2 Cytotoxic effects of various antisera plus complement on non-dividing and on mitotic T and B lymphocytes

The assessment of cytotoxic activity on mitotic lymphocytes of the various antisera was carried out as described previously¹⁶ and shown in Fig. 1. Just before mixing the antiserum-treated CBA/Lac cells with the control treated CBA/T6T6 cells, a small aliquot was withdrawn and assayed for the % cells killed by the dye exclusion method. Control treated CBA/Lac cells were also tested and the cytotoxic index calculated. An equivalent aliquot was withdrawn from the CBA/T6T6 cell suspensions to control for cell loss before mixing and cytological analysis. Draining axillary lymph nodes or spleens were removed 3 d after stimulation of the mice. In all cases 250 μ l of neat antiserum was used to treat 5×10^6 nucleated cells except in the case of anti-MBLA, where only 100 μ l was used. This gave a lower cytotoxic index than is usually obtained and may account for only 84% of the LPS activated mitotic cells being killed.

*The anti- θ_{C3H} serum which is specific for T cells¹ was prepared as described previously¹⁶, and its properties have been described elsewhere¹⁶.

†The anti-H2 serum was made by injecting Balb/C (H2^a) with 20×10^6 spleen cells from CBA (H2^b) donors at weekly intervals for 6 weeks and bleeding the mice 1 week after the last injection.

‡The anti-MBLA serum which is specific for B cells after absorption was made according to the method of Raff *et al.*¹⁵ and absorbed with M γ G as well as thymocytes.

Table 3 Cytotoxic effects of anti- θ serum or anti-immunoglobulin serum plus GPC on mitotic lymphocytes activated *in vitro* by PHA or *E. coli* LPS

Experiment	Mitogen	Serum treatment of spleen cells from:		Cytological analysis		Ratio of Lac/T6T6	% Kill by antiserum
		CBA/Lac cultures	CBA/T6T6 cultures	CBA/Lac	CBA/T6T6		
1	PHA	a anti- θ	NMS	6	94	0.064	90.4
		b NMS	NMS	40	60	0.667	
2	PHA	a anti-Ig	NRS	35	65	0.538	— 9.1
		b NRS	NRS	35	67	0.493	
3	LPS	a anti- θ	NMS	33	67	0.493	21.8
		b NMS	NMS	39	61	0.639	
4	LPS	a anti-Ig	NRS	39	61	0.639	8.1
		b NRS	NRS	41	59	0.695	

On day 0, CBA/Lac or CBA/T6T6 spleen cells were incubated with either PHA or LPS in a manner as previously described (1×10^6 cells per culture)²⁰. On the evening of day 2 colcemid was added to each of the cultures and they were collected 16 h later. Using experiment 1 as an example, 5×10^6 PHA activated CBA/Lac spleen cells were incubated with 0.25 ml of neat anti- θ , followed by 0.5 ml of 1:8 GPC. The surviving cells were mixed with 5×10^6 PHA activated CBA/T6T6 spleen cells which had been treated with NMS+GPC and the mixture was then subjected to cytological analysis. In 1a, only six of the mitotic figures counted were CBA/Lac in origin. A control mixture (1b) in which both the CBA/Lac and CBA/T6T6 cells were treated with

NMS+GPC, showed that 40 of 100 mitotic figures were CBA/Lac in origin. The % kill by anti- θ was calculated by subtracting the ratio of CBA/Lac to CBA/T6T6 figures in the anti- θ treated mixture from the ratio found in the NMS mixture, dividing by the ratio found in the NMS mixture

and multiplying by 100, that is $\frac{0.667-0.064}{0.667} \times 100 = 90.4\%$ kill

of PHA activated CBA/Lac mitotic cells by anti- θ +GPC treatment. A similar procedure was done where anti-Ig was used. In these cases 5×10^6 PHA or LPS activated spleen cells were incubated with 0.25 ml of anti-Ig at 0°C for 1 h before the GPC was added.

compromise the use of such antisera in such cases. This in turn suggests a means by which it may be possible to 'negatively' select for (and subsequently isolate) a small number of specifically activated B cells. Treatment of a population of antigen-activated, colcemid-treated, lymphoid cells by anti-Ig plus complement should kill all B cells except those arrested in metaphase, and the majority of these mitotic cells should have specificity for the activating antigen.

We thank Dr A. J. S. Davies for criticism and advice, Dr E. Golub for suggestions, Dr V. Schirmacher for providing anti-MBLA serum and MyG coated sepharose particles, and Dr Tessa Sadler for providing thoracic duct cells. This work was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council and the Cancer Research Campaign. R.S.K. is a research Fellow of the National Cancer Institute of Canada.

Note added in proof: Preliminary electron microscope studies using immunoperoxidase staining have revealed that mitotic B cells do in fact contain large amounts of cell surface Ig molecules, similar to that found on resting B cells.

Yeast-mycelial conversion induced by N-acetyl-D-glucosamine in *Candida albicans*

DIMORPHISM in fungi is generally defined as a reversible transition from a yeast habit of growth (Y) to a mycelial one (M)¹. In *Candida albicans* Y→M transition can occur rapidly in serum^{2,3}, serum substitutes and other natural⁴⁻⁶ and synthetic media⁷. In a few hours the yeast cell or blastospore forms a germ tube which grows as a true mycelium^{8,9}. Since the cellular form depends on wall construction¹⁰, marked modifications in the organisation of wall components are expected to, and in fact do, occur during morphogenesis. Nevertheless, there is chemical¹¹, cytochemical and ultrastructural evidence^{12,13} that the differences between Y and M walls of *C. albicans* are essentially quantitative, strongly suggesting that hyphal conversion in this yeast is controlled by the modulation of pre-existing enzymatic activities rather than by any new factors.

In view of the usefulness and reliability of germ-tube formation in *C. albicans* as a model of hyphal morphogenesis, it is unfortunate that most of the media so far used are too chemically complex to enable an understanding of the biochemical basis of this phenomenon. We are therefore investigating the minimal requirement for germ-tube formation and show here that acetylglucosamine meets this requirement. We shall also discuss a working hypothesis for a possible role of chitin synthetase in the mycelial conversion of *C. albicans*.

Strain A_{IF} of *C. albicans* (Robin) Berkhout was grown as described elsewhere¹³. A standard inoculum of 0.8×10^8 cells (essentially pure blastospores from the late logarithmic phase of growth) was given to a mixture containing the test substances, at the desired concentrations, dissolved in H₂O or in buffer imidazole-HCl 0.01 M, pH 6, 7 (standard), in a

Fig. 1 Germ tubes from blastospores of *C. albicans* after 5 h of incubation in imidazole-HCl buffer, 0.01 M, pH 6.6 containing acetylglucosamine 2.5 mM and MnCl₂ 0.1 mM. The arrows point to cells with two germ tubes ($\times 500$).

final volume of 1 ml. After temperature equilibration, reagents were added and the mixture kept under slight but constant agitation at 37° C. At fixed time intervals, a drop of cell suspension was examined under the light microscope for germ-tube formation, this being recorded as the percentage of elements having at least one recognisable germ tube per 200 elements, regardless of the length of the tube. N-acetyl-D-glucosamine (standard *purissimum*) was obtained from Fluka, Switzerland. All other substances employed were of standard reagent grade.

Owing to the heterogeneity of the initial blastospore suspension, the process of germ-tube formation was essentially asynchronous but in appropriate inducing conditions (see below) after 5 h more than 90% of the cells showed a germ tube of variable length, with many germ

Table 1 Potentiation or inhibition of acetylglucosamine-induced germ-tube formation in *Candida albicans*

Inducer (2.5 mM)	Medium and ions	Other substances	Germination (%)
absent	H ₂ O; Mg ²⁺ or Mn ²⁺ (0.1 mM)	—	3–5
absent	imidazole-HCl Mn ²⁺ (0.1 mM)	—	6–8
present	H ₂ O	—	40–42
present	imidazole-HCl	—	44–47
present	H ₂ O; Mn ²⁺ (0.1 mM)	—	60–65
present	imidazole-HCl Mn ²⁺ (0.1 mM)	—	74–78
absent	imidazole-HCl	cysteine (1 mM)	0
present	imidazole-HCl	cysteine (1 mM)	0

Germination values were taken from two independent determinations, after 4 h incubation at 37° C. Imidazole-HCl buffer was used at pH 6.7 and acetylglucosamine-water measured approximately pH 6.65.

Fig. 2 Time course of germ-tube formation induced by acetylglucosamine 2.5 mM, alone (—●—●—●—), plus MgSO₄ 0.1 mM (—■—■—■—), or plus MnCl₂ 0.1 mM (—▲—▲—▲—). Tests were carried out in imidazole-HCl buffer 0.01 M, pH 6.6, at a temperature of 37° C. Values are means of two independent determinations.

tubes appearing as true hyphae (Fig. 1). The time course of germ-tube formation in various conditions of stimulation with acetylglucosamine is shown in Fig. 2. The germination curve took a sigmoid shape, the maximum rate being recorded between the second and the fourth hour of incubation. The addition of 0.1 mM MgSO₄ or MnCl₂ greatly enhanced the germinating effect of acetylglucosamine (slightly more evident with Mn²⁺). But higher doses of these ions caused no activation but instead a variable degree of inhibition, which is maximal (germination completely abolished) in the presence of 20 mM Mg²⁺ or 25 mM Mn²⁺. Germination did not occur in phosphate Na/K buffer 0.1 M even at high doses of inducer (50 mM) and the same imidazole-HCl buffer was somewhat inhibitory when used at a concentration (0.5 M) higher than that of the standard reaction mixture. Therefore, considering the lack of specificity of these ionic inhibitors, it seems likely that germ-tube formation is sensitive to a high ionic strength. Indeed, high levels of germination can be induced by acetylglucosamine in plain water. Both in water and in imidazole-HCl buffer, the presence of 0.1 mM cysteine completely suppressed the germination (Table 1).

Acetylglucosamine behaves as a strong and rather specific inducer. At 20 μ M it causes, in the presence of 0.1 mM Mn²⁺, 20 to 25% germination after 2 h at 37° C; in this case, however, the phenomenon does not reach completion, even if the mixture is incubated for long periods (12 h). The minimum necessary concentration to achieve full germination falls in the range 0.8–1 mM. Of the analogues tested for their effect on germination (glucose, glucosamine, galactosamine, fructose, glucose-1 phosphate and acetyl-galactosamine) none had any effect until a concentration of 20 mM was reached; at 50 mM, glucosamine and acetyl-galactosamine showed a very slight effect (5 to 8% of germination) of the same order of magnitude as that recorded by incubating blastospores in Mn²⁺-enriched imidazole buffer in the absence of acetylglucosamine (Table 1).

As shown in Fig. 3, the useful ranges of temperature and pH for acetylglucosamine-induced germination in *C. albicans* are rather narrow, the optima falling at around 37° C at pH 6.6. In particular, the germination was markedly low or absent at alkaline pH, at variance with what occurs in serum or other media^{3,6}.

Fig. 3a Temperature dependence of *C. albicans* blastospore germinations induced by acetylglucosamine 2.25 mM in imidazole-HCl 0.01 M, pH 6.6 containing Mn²⁺ 0.1 mM. Effect of pH on germ-tube formation by acetylglucosamine 2.25 mM in imidazole-HCl buffer with (—●—●—●—) or without (—▲—▲—▲—) Mn²⁺ 0.1 mM. The tests were performed at 37°C. Values are means of two independent determinations.

Thus even at very low doses, acetylglucosamine, unlike related carbohydrates, can induce significant germination in the absence of other carbon and nitrogen sources. This, together with consideration of the experimental conditions under which acetylglucosamine induces germ-tube formation in *C. albicans* suggests a specific activating role for acetylglucosamine.

While appropriate experiments must still be performed before an understanding of the mechanism of acetylglucosamine action is reached, we shall consider the possibility that acetylglucosamine directly triggers some key reaction in the dimorphism in *C. albicans*. An obvious candidate for such a role is the chitin synthetase because N-acetyl-D-glucosamine is both the monomer and a specific activator of such an enzyme in yeasts (and other fungi)¹⁴⁻¹⁷.

A controlled activation of chitin synthesis could be a simple way to meet the requirement for increased chitin content of the emerging germ tube and of the hyphal wall¹¹⁻¹³. In *Mucor rouxii*, acetylglucosamine is incorporated, through its UDP derivative, into chitin and it has been observed that chitin synthetase activity is highest at hyphal tip¹⁵. The experimental conditions under which acetylglucosamine induces germ-tube formation in *C. albicans* are comparable to those reported as characteristic of a chitin synthetase assay *in vitro* (pH range, activation by Mg²⁺ and Mn²⁺, specificity)¹⁴. Certainly, as shown in studies on septum formation, the cellular control over chitin synthesis may be highly sophisticated¹⁸ but it is attractive, in line with the results reported above, to think that the levels of free acetylglucosamine in the cell may have a part in controlling overall chitin synthesis and, consequently, germ-tube formation in *C. albicans*. It is also worthwhile to note, in view of the classical concepts on the control of morphogenesis by Nickerson and Falcone^{19,20}, that acetylglucosamine-induced mycelial conversion cannot occur in the presence of an adequate amount of SH compound such as cysteine.

Regardless of these speculations, we have here described an experimental system which is very simple and quite amenable to direct biochemical investigations aimed at an understanding of the biochemical basis of mycelial conversion in *C. albicans*. These investigations may support or

rule out a role for chitin synthetase in this phenomenon.

Early visual adaptation in goldfish retinal ganglion cells

THE human visual system responds with transient losses of sensitivity when background light levels are suddenly increased or decreased. Crawford¹ measured the early threshold changes in humans by means of a small circular test flash presented before, during and after presentation of a larger diameter adapting light. He found that threshold increased just before the onset of the adapting light, reached a peak shortly after onset, and then decreased during the subsequent 0.5 s. Immediately before the offset of the adapting light, threshold increased slightly, peaked at offset and then returned to its original level. Other investigators have reported essentially the same results under various conditions²⁻⁴. The increase in visual sensitivity during the first few seconds of light adaptation and the peaked loss of sensitivity at the offset of the adapting light are in the wrong direction as predicted by bleaching of the photopigments. Consequently, Baker⁵ suggested that neural factors account for the early change in visual adaptation. Unfortunately, the question of mechanisms involved to account for these rapid changes in visual sensitivity cannot be

answered from psychophysical experiments since the response range cannot be assessed during these periods.

We examined the transient losses of sensitivity at onset and offset of an adapting light in thirteen isolated retinal ganglion cells of the goldfish *Carassius auratus* by extracellular recordings with tungsten microelectrodes. The preparation was an open eye intact procedure developed by Adams⁶. The apparatus, recording procedure and methods have been described previously^{7,8}. All ganglion cells were opponent types; the centre of each cell's receptive field received an inhibitory input from receptors containing a photopigment whose maximum absorption was at 625 nm and excitatory input from receptors containing a photopigment whose λ_{\max} absorption was at 530 nm (refs 6, 9). All cells had a central receptive field area of diameter about 1 mm on the retina and a surround larger than 3 mm. The tests and adapting stimuli were focused directly on to the centre of the cell's receptive field under steady photopic background conditions. A 480 nm test light was chosen to stimulate the $\lambda_{\max} = 530$ nm excitatory cone system, while a 570 nm adapting light was chosen because there is an equal quantal absorption at this wavelength by the two goldfish cone photopigments¹⁰.

Fig. 1 Intensity response function of the excitatory mechanism of a light adapted opponent, (-R/+G) cell before and 500 ms after onset of an 0.5 mm adapting light of 570 nm containing 3.6×10^{15} quanta $\text{s}^{-1} \text{cm}^{-2}$ (abscissa represents log test irradiance of 480 nm, 0 corresponds to $7.2 \times 10^{14} \text{s}^{-1} \text{cm}^{-2}$). The mean of 10 incremental responses measured in spikes s^{-1} above the spontaneous level during the 0.5 s presentation of the test spot is plotted on the ordinate (dotted line 0 corresponds to the normalised spontaneous level in both figures). ●, Measured at steady photopic levels ($2.2 \mu\text{W cm}^{-2}$), spontaneous level being 23 ± 5 spikes s^{-1} . ■, Response function at 0.5 s after onset of the 570 nm adapting light presented at the same photopic background; spontaneous level at this time being $31 \pm$ spikes s^{-1} .

The sensitivity of the excitatory mechanism at various times before, during and after the presentation of adapting lights parallels those seen in human psychophysical experiments, although the time course is longer in this cold blooded vertebrate retina^{7,8}. We measured the intensity response function during the periods when these cells showed a transient loss of sensitivity (Figs 1 and 2). The effect of the onset of the adapting light on a cell's intensity response function is shown in Fig. 1. A smooth curve drawn through the intensity response function at a steady background level illustrates the range of about 1 log unit from threshold to the peak response (in Fig. 1). We refer to threshold-to-peak and not saturation because at higher an intensity level than the peak response the inhibitory 625 nm cone system input reduces the peak response. Adapting light of wavelength longer than 570 nm selectively depresses the sensitivity of the $\lambda_{\max} = 625$ nm cone system and increases the threshold to peak response range⁸. The curve is shifted to overlap the intensity response function measured at 500 ms after the

Fig. 2 Intensity response function of the excitatory mechanism of a light adapted opponent (-R/+G) cell. ●, Response function at photopic levels of $2.2 \mu\text{W cm}^{-2}$, spontaneous level being 9 ± 3 spikes s^{-1} . ▲, Response function at the same photopic level when a 0.5 mm adapting light of 570 nm containing 3.6×10^{15} quanta $\text{s}^{-1} \text{cm}^{-2}$ has been on for at least 5 min, spontaneous level is 16 ± 4 spikes s^{-1} at this time. X, Response function at photopic levels 0.75 s after the offset of the 0.5 mm adapting spot of 570 nm light, spontaneous level at this time is 30 ± 5 spikes s^{-1} . (Abscissa represents log test irradiance of 480 nm, O corresponds to $7.2 \times 10^{14} \text{s}^{-1} \text{cm}^{-2}$.)

onset of the adapting light. The intensity response function has shifted to the right on the intensity axis, about 1.5 log units, but the range from threshold-to-peak is unaltered. A similar shift in the intensity response function occurs at the offset of the adapting light as illustrated on a different cell in Fig. 2. The intensity response function at a steady background level is shown for comparison. The steady 570 nm adapting light decreased the sensitivity by about 0.5 log units as illustrated by the shift of the intensity response function to the right on the intensity scale. At the offset of the 570 nm adapting light, the sensitivity was further depressed and the range of response is further shifted to the right on the intensity axis. Although it is not shown in Fig. 2, after 3–5 min the response function shifted back to its pre-adapted position. The important generality expressed in these specific examples is that under all conditions of adaptation, transient and steady state, the range of incremental response from threshold to peak remained the same.

The early loss of sensitivity at onset and offset of an adapting light in these experiments was not due to a compression of the response function or a saturation effect at the ganglion cell. The range of light intensity necessary to elicit a threshold to peak response was the same immediately after onset or offset of the adapting list as in steady state conditions. The response function shifted when plotted on a log intensity axis and maintained its general shape and slope. The results show that in these ganglion cells, the operating range shifts across the intensity axis, consistent with a gain change.

The knowledge that gain changes occur in the visual system is neither new nor unexpected, and has been shown in many physiological experiments involving both field and bleaching adaptation^{11–15}. Previously, however, the gain changes, as measured by a cell's response function, were assessed at steady stages of light and dark adaptation where photochemical events are monotonically related to sensitivity. The early threshold events of light and dark adaptation in man are not monotonically related to photochemical events and have been presumed to be limited by neural events. However, in the ganglion cell of the goldfish retina, we have found that the early adaptation events are best described as gain changes and are similar to the change in gain which occurs in the later stages of light adaptation. The signals

from amacrine and horizontal cells show a transient change in the resting potential with the onset and offset of light consistent with the observed shift in the ganglion cell's response function¹⁶. The signal from either of these cells may be involved in the rapid translation and return of the ganglion cell response function across the intensity axis.

Since the early visual sensitivity changes in the human closely parallel those seen in the ganglion cell of the goldfish retina, gain changes may also be responsible for the early transient sensitivity changes observed in humans.

Carcinogenicity of bracken and shikimic acid

SINCE our initial reports of the carcinogenic potential of bracken for rats and mice^{1,2}, part of our work has been directed towards the isolation of the causative factor(s). The assays used have included acute toxicity testing in mice (orally and intraperitoneally (i.p.)) and mutagen trials with *Drosophila* and mice, as well as long term cancer induction in rats and mice. The former suffer from the disadvantage of being nonspecific for carcinogens and the latter from the delay of a year or 15 months before results can be assessed. A fraction was isolated, however, which proved positive for acute toxicity, mutagenicity and carcinogenicity in mice and the preliminary molecular formula of $C_7H_8O_4$ was given for the main constituent^{3,4}.

We have now carried the chemical characterisation further and after correction by a low temperature mass spectrum (the addition of a molecule of water to bring the molecular weight to 174 ($C_7H_{10}O_5$)), the full analysis gave clear evidence that the isolated compound was shikimic acid (3,4,5 trihydroxy-1-cyclohexene-1-carboxylic acid). The detailed report on the chemical elucidation will be given elsewhere.

At first sight, shikimic acid does not seem to be a likely candidate for a carcinogen, it is widespread in plants⁵, being on the biosynthetic pathway of aromatic ring compounds, and it does not fall readily into the well known groups of chemical

substances which can induce cancer in experimental animals. Considerable effort was therefore devoted to the minor constituents of the fraction as revealed by chromatography, but fortunately shikimic acid was not entirely neglected and single administrations of the commercially produced acid of tested purity (BDH Ltd) were given to mice. We now have to report the results, to date, of this experiment which are shown in Table 1.

TF1 strain mice (Tucks), averaging 10 weeks of age, were given single i.p. injections of aqueous shikimic acid. Later groups have been dosed orally by stomach tube and the first fatality among these is listed in the table. Out of 14 animals, 9 had cancerous and precancerous lesions. A total of 57 control mice were treated in the same way with various inert materials in aqueous solution and killed after comparable periods of time. It is important that none of these animals had any neoplasms at all, as it indicates that for this strain of mice the spontaneous tumours of old age are not encountered at ages of 15 months or less.

The leukaemias are classified according to the system described by Dunn⁶, and display the variety of classic features including widespread dispersal through the peritoneal and pleural cavities and involvement of organs such as lymph nodes, spleen, liver, and kidney. The reticulum cell A leukaemia was extremely disseminated, with the elongated and round cell types equally represented. One of the reticulum cell B leukaemias had binucleate giant cells and also a greater mixture of plasma cells with the lymphocytes than usual. Grade I neoplasms of the glandular gastric mucosa include those changes which are limited to the mucosa itself, whereas in grade II invasion through the muscularis mucosae into the submucosa has taken place to give the typical 'carcinoma in situ'. In two of the latter, intestinalisation of the tumour epithelium had also taken place.

In the light of these results a mouse test for the production of dominant lethal mutations was conducted according to the method of Bateman⁷, five mature male mice (TF1 strain, averaging 10 weeks old with weights 25-30 g) were used in each test group and ten injected with 0.5 ml of physiological saline for control figures. One group was injected (i.p. with 25 mg of shikimic acid in 0.5 ml of water, which is approximately the LD₅₀ dose (1000 mg kg⁻¹), and a second group had an oral dose administered by stomach tube of 80 mg in 0.2 ml of water. For the 8 successive weeks of the spermatogenic cycle, the males were mated with four virgin females. These were removed at the end of each week and kept until the 12th day from the midweek of their mating, when they were killed, the uterus removed and scored for total implantations, early deaths indicated by deciduomata, and late deaths.

The results are plotted as the percentage of dead implants against weeks from injection (Fig. 1). The percentage, which has

Fig. 1 Dominant lethal mutations induced in mice by commercial shikimic acid. ●, 25 mg (intraperitoneal injection); ○, 80 mg (stomach tube); ▲, control.

also been termed the Mutagenic Index, is derived from the formula:

$$(\text{deciduomata} + \text{late deaths}) / \text{total implants} (\times 100).$$

Each weekly figure is based on the results from 20 females and the numbers not pregnant will decrease the accuracy. It is important that total implants should exceed 100, and in the 16 shikimic groups they averaged 163 (104–210), while the controls averaged 171 (115–237). Taken over the whole 8 weeks, the average control figure was 4.4% (3.2–5.4), whereas the oral shikimic group reached a peak of 13.6 and those injected i.p. were consistently high from the second week onwards, reaching a final maximum of 22.1%.

It is interesting to compare these results with those of Epstein and Shafner⁸ investigating the mutagenic effects in mice of a variety of environmental pollutants, including carcinogens, with an almost identical experimental design. The main difference is that their control mice had an average dominant lethal rate of 1.0% (0–3) while our corresponding figure was 4.4%.

On the other hand, the dosage was of the same order, approximating to LD₅₀ in both cases. On this basis, of the carcinogens listed, only aflatoxin and benzo-a-pyrene reach a level of dead implants of 11% and of all the groups of compounds only METEPA (ref. 8) and related pharmaceuticals reach into the 20% range.

The long term results from previous experiments are now showing clearly that there is a second and different fraction derived from bracken which contains a strong carcinogen and is also capable of inducing the syndrome of acute bovine bracken poisoning (I. A. E., R. S. Jones, D. L. Jones and W. C. Evans, unpublished). That this agent is a more powerful tumour inducer

in mice than shikimic acid is indicated by the fact that single administrations (i.p. and orally) will produce malignant squamous carcinoma of the forestomach as well as the glandular gastric tumours. As well as investigating this fraction, the trials on shikimic acid are being extended to include its effects on other experimental animals and daily small oral dosage as opposed to the single administration tested so far.

We are grateful for financial support from a Cancer Research Campaign grant, the World Health Organisation, Veterinary Division, and a postgraduate research scholarship from Cairo University, Egypt. The low temperature mass spectrum was by courtesy of Drs A. McCormick and C. Baker Harwell.

Phylogenetic origin of xenogeneic recognition

SINCE Metchnikoff (quoted in ref. 1) showed that amoebocytes, the circulating cells in invertebrates, are capable of phagocytosis¹, it has become increasingly apparent that they have various immunological functions. For example, amoebocytes mediate resistance to infection^{2,3} and rejection of xenogeneic grafts^{4,5}.

We have described recognition at the cellular level in the northern sea star, *Asterias vulgaris* (Echinodermata). These animals distinguish between autologous, allogeneic and xenogeneic cell challenge, as evidenced by the development of clumping, and a corresponding decrease in the number of circulating single cells, a phenomenon occurring only in the xenogeneically challenged host. Xenogeneic cells could also be identified in these large multi-cellular clumps⁶.

In addition to host clumping, which is a mechanism of trapping foreign cells, we were interested in determining whether there was a second component to the response, for example, a humoral as well as cellular reaction to foreign antigen. We have now found that a soluble factor which mediates *in vivo* cell aggregation is released by the host in response to xenogeneic but not allogeneic cell challenge.

Common sea stars (*Asterias forbesi*) collected near the Marine Biological Laboratory, Woods Hole, were maintained in tanks containing circulating seawater. Variation in the concentration of unclumped amoebocytes in coelomic fluid fluctuated very little over 60 min (Fig. 1).

Thirty sea stars were inoculated with various cell preparations, both of allogeneic and xenogeneic origin. All 15 xenogeneically challenged animals had decreases in circulation cell counts of greater than 90%. In addition, eight sea stars were evaluated in their initial response: 5 min after challenge when clumping was maximal and the circulating cell count had reached its nadir, the tips of two arms were cut, and the coelomic fluid containing the

Human RBC	7.5 × 10 ⁵	2.0 × 10 ⁵	27	1.8 × 10 ⁶	4.0 × 10 ⁴	2

Sea stars were inoculated with 3.0 ml seawater, 1×10^8 carbon particles, 1×10^6 sea urchin amoebocytes, 1×10^6 horseshoe crab amoebocytes, or 1×10^8 human red blood cells. Stars were counted just before inoculation (time 0 (A)) and 5 min after inoculation (time 5 (B)). Percentages of single cells (B/A × 100) were determined. Precounted naive animals were then inoculated with 1.0 ml cell-free supernatant from the challenged sea stars, 5 min counts were obtained, and percentages (B/A × 100) determined.

* Numbers represent single amoebocyte count per ml coelomic fluid.

cells was collected. It was then centrifuged for 20 min at 280g and 1.0 ml of cell-free supernatants (as verified by microscopy) inoculated into a secondary 'naive' recipient. The concentrations of single amoebocytes in the recipient was determined before and at intervals after inoculation.

As Table 1 shows, when either seawater or sea star 'allogeneic' cells were used as challenge inocula, clumping did not occur either in the challenged animal or the passively transferred recipient. Inoculations of sea urchin, horseshoe crab or human peripheral blood cells resulted in a sharp decline in the circulating cell count. Supernatants from positive responders in turn initiated the same response in naive recipients. An example of the response of sea stars treated with cell-free supernatants from either non-reactive or reactive animals is shown in Fig. 2. Only when clumping occurred in the xenogeneically challenged animal was there a corresponding decline in single cell concentration of the passively transferred recipient. Carbon particles induced a moderate clumping response which could be transmitted in the supernatant, indicating that host responsiveness rather than lysis of inoculum was primarily responsible for subsequent *in vivo* clumping.

Prendergast⁷ has isolated a protein (SSF) with a molecular weight of 32,000 from the amoebocytes of the sea star which he has shown mediates clumping in sea stars treated with SSF. It is possible that the factor mediating *in vivo* amoebocyte clumping when transformed to secondary recipients in our system, may cross react with SSF.

The data suggest that recognition in echinoderms is char-

Fig. 2 Sea stars were inoculated with 1.0 ml cell-free supernatants from animals given either 3.0 ml seawater (●) or 1.0×10^6 horseshoe crab amoebocytes (★). Circulating single cell counts were determined over 1 h.

acterised by the following *in vivo* sequence: (1) distinction of xenogeneic antigen; (2) release of activator; (3) clumping, and (4) trapping of xenogeneic cells. The mechanism of host distinction between allogeneic and xenogeneic antigen is unclear. It is becoming apparent, however, that at this stage of phylogeny xenogeneic rather than allogeneic recognition is an intrinsic property of the relatively undifferentiated amoebocyte in contrast to vertebrate and mammalian lymphocytes which respond vigorously to alloantigens.

matters arising

Turtle drift

SIR,—It occurs to me that the origin of the peculiar migration pattern of the green turtle, *Chelonia mydas* may be otherwise than suggested by Carr and Coleman¹. They argued that since the early Cretaceous certain turtles have inherited a tendency to swim a particular WNW–ESE path from Brazil to the Ascension Islands, swimming against the prevailing current for about eight weeks. They note, however, that *Chelonia*, which is a herbivorous, frequently seagrass ('turtle grass') eating form, is not recorded before the Miocene. This concurs with my observations² on *Thalassia* (turtle grass) and its associated biota which did not succeed in reaching the tropical Americas until the early Miocene. It seems likely that these seagrasses came from the Indo-Pacific through the southern tip of Africa, and drifted passively across to Brazil from West Africa on the equatorial surface current. Therefore seagrass feeding grounds at least, were situated on the eastern side of the Atlantic first. One might infer from this that the herbivorous turtles followed the seagrass biota westwards across the Atlantic (through the mid-oceanic islands) but returned for the breeding season. If this is so, then the early ancestors of *Chelonia mydas* should be found in Africa or further east.

A second consideration is that the behavioural pattern suggested by Carr and Coleman seems to make little ecological or evolutionary sense (which they have almost admitted). They imply that the home breeding grounds around South America became inexplicably untenable (presumably many millions of years after turtles had become established) so favouring a change in behaviour in these otherwise ultraconservative creatures. The progeny produced by this 'freakish' behaviour were then lucky enough to drift back to the old feeding grounds on the current. Bearing in mind the extremely conservative breeding behaviour of past and present amphibians and primitive reptiles I feel this postulation will need a more thorough explanation.

Would it not be more in keeping with the evidence to postulate the passive drifting of juveniles westwards across the Atlantic (where, after the Palaeogene they would have found plentiful seagrass) followed at breeding

time by a homing instinct that leads them eastwards to the midoceanic islands? The seafloor spreading part of their hypothesis would work equally well.

No radioactive silver detectable in silver–uranium ore

SIR, — Lindner *et al.*¹ have reported finding the radioactive silver isotopes ^{108m}Ag and ^{110m}Ag in silver bars of eastern European origin, and have conjectured that the silver may have been mined using nuclear explosives. Boyle² has suggested that it was more probable that the radioactive silver had been produced by neutrons from (α , n) reactions and spontaneous fission reactions of uranium in the silver ores. In January 1974, I was able to secure a sample of uriferous silver ore from a mine at Contact Lake, North West Territories, near Port Radium on Great Bear Lake. The 70 g sample was crushed and ground. The resulting powder was assayed using X-ray fluorescence spectroscopy and was found to contain 6.8% Ag and 0.97% U. Fifty grams of the powder was roasted, treated with HF and H₂SO₄, leached with HNO₃ and the extracted silver was precipitated as the chloride. Four grams of AgCl, corresponding to 3 g of Ag, was counted in a defined geometry on a large, high resolution, low background Ge(Li) detector for 25 h. No silver gamma peaks were detected.

The 25 h background of the detector in the region of the 658 keV ^{110m}Ag γ ray was 110 counts. Using the detection limit³ of $4.65\sigma_B$, where σ_B is the standard deviation of the background for paired observations, gives a detection limit of 50 counts in the peak.

Lindner *et al.*¹ found that the silver bullion contained 84 pCi of ^{110m}Ag per gram of silver. If this figure is used to calculate the expected number of counts in the same peak, using a 3 g sample of

silver, a 25 h counting time, 94% peak abundance (ref. 4), 48% isotopic abundance of the parent isotope, ¹⁰⁹Ag (ref. 4), and a measured absolute efficiency of the detector of 2.8% for that energy, then the peak would contain 1.1×10^4 counts. The ratio of the ^{110m}Ag found in the bullion to our detection limit for radiosilver from the Canadian ore is $1.1 \times 10^4/50$, or 220. Therefore it seems that Boyle's suggestion that the radioactive silver found in the bullion by Lindner *et al.* was of natural origin is incorrect.

I thank R. R. Wallace for obtaining the ore sample and G. J. Jarbo for the silver and uranium analyses.

ABO matching in kidney graft survival

SIR,—Joysey *et al.*¹ reported on kidney graft survival in Cambridge with particular reference to the ABO group of the recipient. The data from Birmingham confirm these findings and allow a further breakdown by ABO status of the donor.

A system of computer documentation of transplantation and serological data is being used, which includes the display of survival on a graphical plotter. The data are presented in a direct form, showing the fraction of grafts surviving, rather than as 'actuarial' curves. The graphs, therefore, may show irregularities instead of a smooth descending curve. The advantages and disadvantages of various methods of presenting survival data will be discussed elsewhere.

Excluding second and third grafts, 161 patients were transplanted between May 1968 and January 1974 with cadaveric kidneys. Figure 1a shows the survival information in intervals of 3

months over a 4-yr period. All graft failures are included. Survival in group O and non-group O recipients shows the same difference as in the Cambridge data, that is that grafts survive better in group O patients. At 1 yr a 2×2 test shows formal significance, $\chi^2 = 6.49$, $P = 0.02-0.01$; however this test was only made after looking at the graphical output. The group A patients were divided according to whether they received group O or group A donor kidneys, Fig. 1b. There seems to be no initial difference in survival, but the numbers are small.

Fig. 1 Survival of kidney grafts in Birmingham. *a*, Survival in group O (x) and group A (+) recipients. *b*, Subdivision of group A recipients according to whether they received group O (x) or group A (+) kidneys. There were 62 group O recipients; the 75 group A recipients received 51 group A and 23 group O kidneys, and one of unknown blood group. Vertical bars represent standard error.

Only group O recipients are guaranteed an identical ABO match. If a mismatch for the product of the O gene is not acceptable, using the genotype frequencies for southern England from Race and Sanger², this will only account for 14.4% of A to A transplants and 17.4% of O to A transplants because the majority of group As will be heterozygous AO. Is this, together with an allowance for A₁ and A₂ mismatching, enough to account for the observed discrepancy in graft survival between group O and group A recipients? If ABO genotype is important, then without A₁ and A₂ grouping and matching, only 44% of A to A grafts will be genotypically identical.

I am indebted to Professor J. H. Edwards and Mrs Karen Glenn for developing the system of computer documentation.

I thank Mr A. D. Barnes for making the survival information available and the Kidney Research Fund for financial

assistance with the analysis.

Spittlebug morph mimics avian excrement

SIR,—Most colour forms^{1,2} of the spittlebug, *Philaenus spumarius*, are cryptic, but the *marginella* morph has a black body outlined by white. Thompson³ has proposed that this phenotype represents an example of escape warning coloration, suggesting that experienced predators ignore *marginella* individuals because they remember previous "frustrating encounters" with *marginella* more vividly than similar encounters with cryptic morphs. The logic of this argument is tenuous. It seems equally likely that predators should chase *marginella* more actively because of an equally vivid recollection of successful encounters. Moreover, if the phenotype was a warning pattern its fitness should increase with increased frequency, for a greater proportion of experienced predators would be encountered. Both cryptic and *marginella* forms must be present for such conditioning, but this is assured even when the *marginella* allele is fixed, for only the females are brightly coloured, males are cryptic². On this basis fixation of the *marginella* allele should occur, yet in natural populations its frequency remains low.

Patterns of black and white have functions other than predator warning; among small arthropods such patterns are frequently associated with excrement mimicry⁴. Indeed the *marginella* pattern, coupled with the elongate shape of *P. spumarius*, produces a convincing resemblance to a bird dropping. Ignoring possible complications, such as the occurrence of other excrement mimics or changes in the grouped abundance of the cryptic morphs, *marginella* frequency should be intimately related to model abundance. A uniform distribution of bird droppings could, for instance, be the cause of the relatively constant frequency of the *marginella* morph in the Great Lakes area of North America².

The frequency-dependent fitness of mimetic forms can lead to sex limitation when the timing of predation differs between sexes. For example, if predation is postreproductive in males, but pre-reproductive in females, suppression of male mimicry allows population size to

increase while not affecting male fitness. This situation is closely approximated in *P. spumarius* as mating occurs in the early summer while egg deposition is delayed until autumn⁵. It is not surprising then, that modifiers have accumulated to restrict the *marginella* pattern to females.

In conclusion there seems little reason to suspect that the *marginella* phenotype has any warning significance; rather it mimics avian excrement in a situation analogous to classical Batesian mimicry.

Yours faithfully,

PAUL HEBERT

School of Biological Sciences,

⁵ Wiegert, R. G., *Ecol. Monogr.*, **34**, 217 (1964).

MR THOMPSON REPLIES: I believe these objections to my proposal are not well founded. Cryptic coloration of all forms is not necessary for the maintenance of an apostatic polymorphism. This can be demonstrated quantitatively by a simple extension of the model of Clarke and O'Donald¹ for frequency-dependent selection at one locus with dominance. Let *A* represent a dominant allele for conspicuous coloration with frequency $1-q$ and *A*¹ a recessive allele for more cryptic coloration with frequency q . Let *t* and *t*₁ represent factors relating the frequency of each phenotype to its selective value, and let *I* be a standard fitness.

Genotypes	<i>AA</i> and <i>AA</i> ¹	<i>A</i> ¹ <i>A</i> ¹
Frequency after random mating	$1-q^2$	q^2
Selective value:		
Case 1	$I-t(1-q^2)$	$I-t_1q^2$
Case 2	$I-t(1-q^2)+w(1-q^2)$	$I-t_1q^2$

At equilibrium the selective values of the two phenotypes must be equal and for this example (Case 1) it can be shown that there is a non trivial stable equilibrium for the two alleles at $\hat{q} = \sqrt{[t/(t+t_1)]}$ provided that *t* and *t*₁ are both positive (each colour form becomes less fit as it becomes more common). Both forms will be maintained in the population with the more conspicuous form at lower frequency.

Furthermore, an allele determining a conspicuous pattern which is also a warning pattern will not necessarily increase to fixation, even though the warning pattern *per se* confers greater fitness as its frequency increases. Let *w* represent the relation between the frequency of the conspicuous phenotype and that part of its selective value determined by its function as a warning

pattern, with t and t_1 again representing apostatic relations (Case 2). In this case there is a non trivial stable equilibrium at $\hat{q} = \sqrt{[(t-w)/(t-w+t_1)]}$ so that when $t > w$ the tendency of the conspicuous warning pattern to increase will be held in check by apostatic selection. Though this example probably underestimates the complexity of the predator-prey relations in question it does demonstrate that there is no *a priori* reason to reject the hypothesis that *marginella* is a warning pattern maintained in polymorphic condition with more cryptic forms by apostatic selection.

Dr Hebert's counter proposal is difficult to accept. The *marginella* pattern of black on white is too sharp and the black on most specimens too unbroken to reasonably suggest a resemblance to bird excreta. But, as Hutchinson² has noted, the colour form *trilineata* may vaguely resemble grass seeds and I do not rule out protective resemblance as a factor in *Philaenus spumarius* polymorphism.

I thank Dr L. Van Valen for comments.

Genetic control of natural resistance to *Leishmania donovani*

SIR,—In studies of infections in mice with *Leishmania donovani*, an intracellular parasite, (in preparation) several observations are relevant to the recent letter¹ on mouse susceptibility to *Salmonella* showing that seven mouse strains fell into two resistance categories.

Colleagues and I have found that the growth rate of *L. donovani* (Ethiopian strain L82) populations in mice varied greatly and examined the acute phase, the first 2 weeks after infection, in detail. Amastigotes from hamster spleen, cleaned by differential centrifugation, were injected intravenously into three mice from each of 25 inbred strains and five F_1

hybrids. Parasite numbers at day 15 in the liver were estimated by Stauber's method^{2,3}. The ratio of parasites to liver cells was determined on liver imprints and multiplied by the liver weight in mg to give a reproducible index of parasite load in LDU (Leishman-Donovan units).

The mean liver parasite load on day 1 of 30.5 LDU did not differ between strains but at day 15 inbred mice fell into two distinct categories which did not overlap. Twelve highly susceptible strains showed about a hundred-fold multiplication whereas the remaining 13 strains were resistant with less than eight-fold increase. No intermediates were seen except for an F_1 cross between a susceptible and a resistant strain which was of intermediate susceptibility. The observation suggested a rather simple genetic control of resistance. Our series included the seven strains studied by Plant and Glynn¹ and the results are in Table 1. There is precise correspondence between resistance to *S. typhimurium* and to *L. donovani*.

In breeding experiments resistant C3H mice were crossed with susceptible NMRI. The F_1 progeny were both selfed and back-crossed to each parental strain. Mice were infected as before. Liver counts from mice killed after 2 weeks are summarised in Fig. 1. Susceptible mice reappear as a distinct group clearly separable from a wider group corresponding to resistant and F_1 categories. The proportion of susceptible mice does not differ significantly from one quarter in the F_2 and one half in the back cross to susceptible parents. Also, the observed distribution of other counts fits closely to the predicted distribution on Mendelian expectations using independent estimates of the means and variances of counts in F_1 and resistant mice.

This is strong evidence for control of *L. donovani* growth in the mouse liver by a single gene or tight linkage group. The coincidence of response pattern to *L. donovani* and *S. typhimurium* has a 1:64 probability of having arisen by chance as there are concordant results for six separate mouse strains (C57BL and B10.D2 are genetically very similar). It is therefore possible that we may be

Fig. 1 Histogram of liver parasite burdens, 14–16 d after infection with 10^7 *L. donovani*, from 16th passage, October 1972. Mice derived from crossing susceptible[†](S) NMRI and resistant (R) C3H strains. Results from F_2 back-crosses (BC) to S and to R, F_1 , and parental strains are shown. Parasite counts have been logarithmically transformed.

dealing with the same genetic mechanism.

There is no evidence from our 25 strains that any $H-2$ alleles correspond with acute phase resistance or susceptibility, nor have attempts to map the gene (provisionally name *Lsh*, leishmaniasis resistance) given support for any linkage to *Ir* or $H-2$ loci (D. J. B. and B. A. Taylor, in preparation). Results so far do not suggest any direct relation of acute leishmaniasis susceptibility to *Ir*1, $H-2$ or the ability to mount an acquired immunological response.

I thank Jean Kirkley for technical assistance and the Royal Society and Wellcome Trust for financial support.

Yours faithfully,

DAVID J. BRADLEY

Table 1 Parasite numbers in mouse livers

Mouse strain	Mean count (LDU)	Mean log count* (\pm s.e.)	Parasite increase (day 15 count / day 1 count)	Susceptibility	
				<i>Leishmania</i>	<i>Salmonella</i> [†]
BALB/c	3,438	3.534 ± 0.030	115.1	S	S
C57BL	3,697	3.565 ± 0.035	123.3	S	S
B10.D2 new	6,410	3.793 ± 0.078	208.4	S	S
DBA/2	94	1.967 ± 0.044	3.1	R	R
C3H/He	165	2.216 ± 0.030	5.5	R	R
A	149	2.170 ± 0.030	5.0	R	R
CBA/Ce	125	2.095 ± 0.040	4.2	R	R

* Here the counts in LDU have been logarithmically transformed which normalises the distribution and renders the variance independent of the mean.

[†] *Salmonella typhimurium* susceptibility from ref. 1 for comparison.

Parasite numbers were measured 15 d after intravenous infection with 10^7 amastigotes of *Leishmania donovani* derived from hamster spleen, 14th passage, May 1972. Three mice of each strain used.

DR PLANT AND PROFESSOR GLYNN REPLY: Bradley's observation that in strains of inbred mice resistance to infection with *Leishmania donovani* is either very high or very low and corresponds to the level of resistance to *Salmonella typhimurium* found by us in six of the same strains reinforces the idea that resistance is controlled by only one or a few closely linked genes.

Like him, we do not find in further breeding experiments that resistance is invariably associated with a particular *H*-2 type. But because of our results with delayed hypersensitivity reactions as well as on general grounds we do believe that some sort of enhanced immune response is involved. Both *S. typhimurium* and *L. donovani* are intracellular parasites and cellular immunity is the most important defence mechanism in both. It is unlikely though not impossible that there is a significant protective antigen common to *S. typhimurium* and *L. donovani*, though it is also unlikely that anyone has actually looked for one. An immune response gene controlling responses to several unrelated antigens would explain the results.

Area postrema and blood pressure

SIR,—Ylitalo *et al.*¹ based their suggestion that the area postrema is a control centre of blood pressure on experiments in which a maintained rise in the level of blood pressure, which was also more labile than normal, followed destruction of the area postrema in rats. As it is well known, however, that such effects are produced by section of the buffer nerves², the possibility must be considered that the baroreceptor pathway could have been interrupted where the sinus and aortic nerves terminate in the medulla in the nucleus of the tractus solitarius^{3,4}, which lies immediately adjacent to the area postrema.

We suggest, therefore, that a simpler explanation of the results¹ is that the damage caused by thermocoagulation of the area postrema had spread the fraction of a millimetre necessary to involve the nucleus of the tractus solitarius. In the absence of evidence that the baroreceptor pathway had been spared, it is not justified to put forward the suggestion that

the area postrema acts as a special blood pressure regulating centre.

On fighting strategies in animal combat

SIR,—The article¹ by Maynard Smith and Price is unfortunately based on a number of unwarranted assumptions, and on an inadequate literature research. It perpetuates an old ethological myth that animals fight so as not to injure each other, or refuse to strike 'foul blows' and, presumably, kill each other. The authors assumed that there were such categories as 'conventional' and 'dangerous' in animal conflict, that opponents in combat retreat when injured, and that opponents retain no memory of past contests. None of these assumptions can be regarded as valid. They were not aware of the published field studies primarily of large mammals which have shown not only how dangerous combat is, but, more importantly, have also led to new theories of explaining aggressive behaviour on the basis of individual selection²⁻¹⁰.

Two authors at least^{2,3,11} have developed the concept that combat can be understood as an interplay of defensive and offensive behaviour. This is a simple point but one missed previously, and one that leads to the conclusion that animals need not rely on altruistic impulses in their opponents to escape injury, but rely on their abilities to block, evade or frustrate attacks. First, the inhibition against engagement in overt aggression in species with excellent weapons but poor morphological or behavioural defences can be explained by the principle of retaliation^{2,3}. This explanation assumes that an animal will attack a conspecific if it experiences severe pain, an assumption amply verified^{12,13}. Second, it assumes that even dangerously armed species (excepting humans) usually cannot kill an opponent outright and thus escape retaliation. This second assumption is entirely in line with data

from diverse field studies on carnivores and ungulates^{2-9,14}.

The authors also become victims of one study of mule deer which can be faulted for inadequate observations. Linsdale and Tomich¹⁵ in their work apparently failed to see a fight between mule deer bucks and confused the common sparring matches with fighting. Sparring matches are performed by bucks of unequal size or dominance rank; they are initiated by the subordinate buck and terminated by him; they are long lasting with many engagements and have antler wrestling as their principal behavioural component. Fights are exceedingly rare, occur between matched bucks, and differ strikingly in their execution from sparring matches; moreover the victor chases and attempts to gore the vanquished. There are no 'winners' or 'losers' in sparring matches. Severe wounding does occur in mule deer, usually on smaller bucks unable to withdraw from onrushing dominants which guard females. Flanks, shoulders, haunches and faces are pierced; the rate of visible wounding is about 10% yr⁻¹ among bucks exceeding 1.5 yr of age. I shall report in detail on this in the near future.

book reviews

Physicist on the pyramids

The Riddle of the Pyramids. By Kurt Mendelssohn. Pp. 224. (Thames and Hudson, May 1974.) £3.50.

DR KURT MENDELSSOHN, the noted cryogenist, has in this book turned his attention to the unrelated subject of Egyptology, in which he confesses an intense amateur interest, and in particular to the riddle presented by the pyramids. Students of the subject may well heave a sigh at the addition of yet another title to the immense literature on Egyptian pyramids which has been written since the days of Herodotus. They may also view with misgiving the entry of a physicist into this unfamiliar field, bearing in mind the intervention of an earlier scientist, Piazzi Smith, the Astronomer Royal for Scotland, who in 1877 produced in his work *Our Inheritance in the Great Pyramid* a source of endless inspiration to the obscurantists who caper on the fringes of the subject. Such fears may immediately be set at rest: Dr Mendelssohn has a unique contribution to make which deserves very careful consideration by the experts as well as the attention of the general reader to whom this book is primarily addressed.

What the author sets out to do is to produce some rational explanation of why such an immense effort was made in raising the great stone pyramids of Egypt over four and a half thousand years ago. The usual explanation advanced by Egyptologists is that such edifices were the tombs of kings who were regarded as gods incarnate, and who according to the religious ideas of the age had to be buried in or under them to ensure the prosperous continuation of the divine government of Egypt. Dr Mendelssohn finds this an inadequate explanation. Some at least of the royal tombs of the Pyramid Age were cenotaphs and what he has to say about this aspect of the problem (pages 74-77) is well worth pondering. He admits that the pyramids served as royal mausolea, not necessarily tombs, but he considers that their funerary function was not the only purpose of their construction, or indeed even the main one.

The point of departure of his enquiry is a discussion of the constructional problems presented by the large stone pyramids at Meidum, Dahshur and Giza. He has already formulated most of his ideas in recent papers in the scientific journals, but in this book

he is able to expand them significantly. The step pyramid which raises its impressive tower above extensive mounds of debris on the desert verges at Meidum was evidently completed by Sneferu, the first king of the fourth Dynasty in about 2600 BC, by adding a cladding of fine limestone, thus converting it to the first true pyramid in Egypt. All the archaeologists who have excavated this monument have agreed that the loss of the outer casing was due to the subsequent operation of stone thieves who used the pyramid as a quarry. Dr Mendelssohn will not accept this finding and has produced impressive testimony to show that the Meidum pyramid collapsed during its final building because its structure had a number of inherent weaknesses. He draws a comparison with the Aberfan disaster; and certainly the aerial view of the pyramid given in his plate 23 clearly shows the plastic flow of the ruined mantle around its nucleus. The shearing-off of this outer covering by such a catastrophe also explains satisfactorily certain architectural features evident in the remaining core and the extraordinarily high mounds of rubble at its base. There are few Egyptologists who will wish to challenge these arguments of Dr Mendelssohn, and pending any final discoveries that may be made by the complete excavation of the pyramid, we may regard his explanation as the most plausible that exists.

The author then proceeds to discuss the effect of this disaster on the design of subsequent pyramids and tries to show that it was responsible for the abrupt change of angle in the Bent Pyramid at Dahshur and for the character of its mantle. He also argues that it promoted improvements in the design of the North Pyramid at Dahshur and the three giants at Giza. If his arguments be accepted, some revision of our views about pyramid building is required since it is clear that two or more great pyramids were being built at the same time during the reign of Sneferu at least, and the implications of all this form the second and more provocative and perhaps more interesting part of the book.

In essence the author's argument is that the consecutive construction of pyramids, one during each reign, is an economic and organisational impossibility. Owing to their immense size the building of pyramids on the scale undertaken in the Fourth Dynasty had become an activity in its own right

demanding its own economic rules. It was the pyramid and not the pharaoh that ruled Egypt; and new pyramids had to be raised whether a pharaoh was ready for burial or not. The erection by the genius of Imhotep of the first great stone building in Egypt, the Step Pyramid of King Djoser in about 2680 BC, began a movement which escalated into a self-sustaining process that affected the seasonal employment of a vast army of workers whose communal feeding, clothing and upkeep for several months during each year must have completely revolutionised the pattern of life for the whole country. A central administration became responsible for the livelihood of a great proportion of the rural and artisan population in place of local councils and village elders. In short, the immense communal activity of building the pyramids created the cohesive Egyptian state with its cohorts of civil servants, and could not be abandoned though it was subsequently modified.

This brief analysis may not do full justice to the author's thesis which is persuasively argued with analogies to the later Mexican pyramids and modern state enterprises. Of course not all the interpretations will command the approval of Egyptologists who form a notoriously sceptical body of opinion; nevertheless we should be grateful to Dr Mendelssohn for obliging us to re-think the received view of the Pyramid Age. One of his readers, at least, will be unable to look again at the monuments of Meidum, Dahshur, Sakkarah and Giza in quite the same old way.

CYRIL ALDRED

Making electricity

Thermionic Energy Conversion. Vol. 1: Processes and Devices. By G. N. Hatsopoulos and E. P. Gyftopoulos. Pp. xi+265. (MIT: Cambridge, Mass. and London, 1973.) \$17.95; £9.00.

THE increasing interest in alternate energy systems makes the appearance of this book apposite; unfortunately like *The Times* it is wise after the event. The method of converting heat to electrical energy described requires thermal sink temperatures high by comparison to room temperature thus making the method suitable in principle for space use. The buildup of the US space programme thus corresponded to a time of intense activity in this field: the rundown of space activity has led to the demise of thermionic energy

Grassland Ecology and Wildlife Management

E. DUFFEY, M. G. MORRIS, J. SHEAIL,
L. K. WARD, D. A. WELLS and T. C. E. WELLS

July 1974: 0 412 12290 1: 304 pages:
tone and line illustrations: hardback: £5.40

This book describes the distribution and ecology of lowland grasslands in Britain with special reference to their flora and fauna, history, and management for wildlife conservation. The maintenance and manipulation of grasslands for agricultural, scientific, conservation and recreational purposes requires an extensive knowledge of the responses of plants and animals to different treatments and disturbance factors. The book examines these in relation to the range of variation in lowland grassland ecosystems and to the known land-use history.

OUTLINE STUDIES IN BIOLOGY

The individual books in the Outline Studies in Biology Series present succinct, authoritative and up-to-date introductions to their subject. They supplement and extend main course texts, and because each book deals with only one topic the series offers the advantage of great flexibility of use.

Brain Biochemistry

H. S. BACHELARD

July 1974: 0 412 12760 1: 72 pages:
illustrated: paperback: 95p

Immunochemistry

M. W. STEWARD

July 1974: 0 412 12450 5: 64 pages:
illustrated: paperback: 95p

Further details of these and related titles, together with a list of stockists, are available from the publishers on request.

conversion. It is therefore difficult to see for whom this book was written; without device requirements it will be of little use to the engineer; it will infuriate the physicist.

Volume 1 is intended to summarise the field and present ideas which will not be changed by subsequent developments. Unfortunately the analogues and the presentation of physical principles do not bring out the excitement of understanding and therefore make it worth undergraduate study; the continued reliance on the statement "a more detailed presentation appears in volume 2" means that the physicist without volume 2 will give up in disgust.

The four chapters of this book present an introduction to thermionic converters, an analysis of ideal performance, a description of vacuum converters and finally a chapter on vapour filled thermionic converters. In what is clearly intended to be a definitive book the brevity of the historical review in chapter 1 is surprising, but most of the various types of converter prior to 1966 are well illustrated. The book has, however, clearly been some time in preparation and converters developed after 1966 are not mentioned. The book is lavishly illustrated, so that the relevant text is often several pages away; it is, however, reasonably indexed, gives a large number of references and contains a useful set of tables and curves. The latter when used in conjunction with the step-by-step instructions given in chapters 3 and 4 give reasonable approximations to observed device characteristics and thus form one of the most useful parts of this volume.

In view of the coherence of presentation suggested by the authors for the complete book, it is perhaps unfair to judge this volume in isolation; however without volume 2 it does not seem worth £9.00.

A. W. PENN

Antibody diversity

The Variation and Adaptive Expression of Antibodies. By George P. Smith. Pp. xii+219. (Harvard University: Cambridge, 1973.) \$12.

THE comparative analysis of amino acid sequences of immunoglobulins has been a major preoccupation of immunologists and molecular biologists for a number of years. The mass of data and the conclusions drawn from this have had a fundamental influence on present ideas on the genetic bases of antibody diversity and the evolution of protein structure. This book presents an exhaustive computer analysis of the data available to the author at the time, in an attempt to define evolutionary relationships.

The book starts with a short survey

of fundamental concepts, intended for readers who are unfamiliar with immunology, and goes on to present tables of all the amino acid sequences that are the subject of subsequent analysis. Unfortunately, since the tables were completed a very considerable amount of important data has been published. In this respect the book is already out of date and does not include an interesting variety of sequences of human, mouse or rabbit κ chains. The analysis of heavy chains fares worst as the book does not adequately cover human μ , α and ϵ chains or mouse γ chains.

A very useful chapter is then devoted to the procedures used for the reconstruction of protein evolution. This provides the reader with a good introduction to the intricacies of the computer programs used. This is followed by an elaborate study of the evolution of C regions. The analysis, although merely confirming accepted ideas, does provide a very balanced view on the reliability of the proposed evolutionary patterns.

The following two chapters are devoted to an exposition of different theories on the origin of antibody diversity and the contrast between the expectations of each theory and the evolutionary patterns derived from the data. The exposition of the theoretical expectations is clear and detailed. The arguments in favour of the germ line theories are presented at their best. This is not the case in the presentation of the opposed arguments. (For instance, the critical discussion on linked parallel mutations (page 103) is only marginally touched on and does not include the possible requirements of tertiary structure.) This is to be expected since the author presents himself as a convinced germ liner.

Three appendices cover references for all the proteins listed, a discussion on allotypes and on ribosomal RNA genes as a model of multigene evolution.

Altogether this is a very readable book which transmits the intellectual excitement of the intricacies of the significance of every possible evolutionary clue. But the problem of antibody diversity is no longer the exclusive domain of protein chemists and the impact of the book is likely to be affected by the success of other approaches. Such new avenues are not properly presented. I was particularly struck by the author's remarks on DNA-RNA hybridisation (page 112): "Conclusive results from this type of experiment depend on the purification of immunoglobulin mRNA . . . a difficult technical feat". Alas, such a "technical feat" was being performed in several laboratories and in fact relevant papers were published at the same time as this book.

C. MILSTEIN

Change in New Guinea

The Chimbu: A Study in the New Guinea Highlands. By Paula Brown. Pp. ix+151. (International Library of Anthropology.) (Routledge and Kegan Paul: London, July 1973.) £3.25.

DR BROWN has, during a period of 15 years, observed the effects of social change in the population of the New Guinea Highlands. This group of people was first discovered by an Australian prospecting expedition in 1933 and many observations were made by administration officials, missionaries and an occasional anthropologist. These records were available to Dr Brown and with her own observations from 1958 onwards, she has been able to make a careful study of the effects of social changes. There is probably no other country in the world where it has been possible to observe profound changes which have occurred over a relatively short time. New Guinea has consequently become a haven for anthropologists but Dr Brown has made one of the most complete studies.

The Chimbu are usually regarded as among the most intelligent and energetic people in New Guinea and as Dr Brown describes, after an initial turbulent period, they seem to be adopting European culture with apparent enthusiasm. The introduction of medical services in recent years has reduced the infant mortality and this, in turn, has caused overpopulation. A few years ago the severe disease kwashiorkor, due to under-nutrition, was prevalent amongst Chimbu infants but this no longer occurs. Local government councils, the introduction of the internal combustion engine for transport and for agricultural purposes, the provision of schools, trading stores, cash crops, missions, European dress, roads, the development of law enforcement and political debating are all part of the new European culture. It is a fascinating story related accurately and entertainingly by Dr Brown.

The 19 chapters of the book are clearly divisible into three parts. The first describes the historic features of the life of the Chimbu people, the second is concerned with the dynamics of tribal life and the third describes many of the effects of change.

A biologist perhaps might be pardoned if he regrets that the biological changes, especially those affecting the growth and development and general health standards of infants and children in the area, were not studied at the same time as the social changes. It is known that such changes have occurred and their correlation with the cultural and social study of Dr Brown would have been interesting. An adjacent area

was the scene of the recent study during the International Biological Programme. Regrettably the latter did not include a study of the effects of social change such as that undertaken by Dr Brown in Chimbu. The problems of communication between different groups of research workers are often as great in New Guinea as in the more advanced countries, and opportunities are lost.

R. J. WALSH

Soviet geology

Geology of the U.S.S.R. By D. V. Nalivkin. Translated from the Russian by N. Rast. Edited by N. Rast and T. S. Westoll. Pp. xviii+855. (Oliver and Boyd (Longman): Edinburgh, November 1973.) £25.

APART from a very slim volume, published in translation in 1960, this is the first and only comprehensive work on the geology of the Soviet Union in English and so, whatever its quality, 855 pages of close type must be taken very seriously. But in relation to the immense geoscientific output from the Soviet Union, with so many multi-volume series on systematic aspects of Soviet geology, this work also is possibly unique in covering so large a field within a single volume.

It suffers a little from age. The interval between 1962 when published in the Soviet Union and late 1972 leaves a time of very great progress in Soviet geology unrecorded. But the value of the work to the English reader is to set the whole range of Soviet geology in perspective in a single framework, which in broad outline at least is hardly affected by recent work. So this volume serves as an introduction for western geologists as well as Soviet students to that vast territory.

The scheme of the book is distinctive, and as in so many general works in Russian science there is a rather explicit philosophy, reflecting scientific as well as political fashion (more than ten years old). In this case the philosophy is made to work throughout the volume. In short it is that geological history can best be understood in terms of geosynclinal development taken in a somewhat comprehensive, genetic and extensive way so as to include many aspects of tectonics including orogeny.

In consequence the book is classified thus: part 1, introduction; part 2, Precambrian geosynclines (Russian platform; Siberian platform; Western Siberian lowlands); part 3, Palaeozoic geosynclines (Uralian geosynclines; Western Arctic geosynclines; Argara geosynclines; Middle Asiatic geosynclines); and part 4, Meso-Cainozoic geosynclines (Mediterranean geosynclines; Pacific Ocean geosynclines).

There is indeed considerable attention paid to these controlling concepts both in the introduction with its historical review of Russian geology and a treatment of such principles, as well as in the translator's introduction. This treatment is indeed quite effective because geosynclines are strata, and the book adopts a thorough and explicit stratigraphical approach to tectonics, magmatism, and useful minerals in each chapter. This coherence is its strength in that a great amount of detail is well organised; it is also well referenced and well indexed.

Because such a unified approach is, with increasing knowledge and specialisation in the Soviet Union, likely to become less and less possible, this work will probably stand without competition as one of the classic regional descriptions, in the line of Heim's *Geologie der Schweiz*, David's *Geology of Australia*, and the recent multi-author Geological Survey work on Canada. Indeed national pride harnessed in this way is most welcome.

Professor Rast is an experienced translator and the work reads well in English. The many photographic illustrations give a sample of varied field conditions in that vast territory directed towards the student population about to explore it. There are a number of attractive sections but as with many Russian works the maps leave much to the imagination. The work is interspersed with innumerable fold-out correlation charts from which are seen, at a glance, both the regional variations and the contemporary Soviet view of stratigraphic classification.

W. B. HARLAND

Genetics practical

Practical Genetics. Edited by P. M. Sheppard. Pp. xii+337. (Blackwell Scientific: Oxford and London, 1973.) £8.50.

FIRST experiences of practical classes in biology are usually traumatic but rewarding for students and teachers alike, for what they observe for themselves often differs from what they were led to expect by plausible lecturers and the pedantry of textbook figures. This is particularly so in genetics practicals where the main technique of crossing and progeny analysis rarely provides the same goodness of fit to expectation which blessed Mendel's results. A working knowledge of statistics goes hand in hand with practical work in genetics and this, coupled with problems of obtaining suitable material, has given rise to the misleading impression that successful practicals are too difficult to organise.

Anyone concerned with teaching genetics at levels between lower sixth

An Introduction to Linear Electric Circuits

L V Kite

This book, with its interesting and unorthodox approach, develops the subject of linear electric circuits from first principles as a self-contained discipline. It requires only the most elementary knowledge of calculus. In the chapters involving alternating currents the reader will, however, require a working knowledge of complex algebra and the complex exponent. £3.95 net

Geometrical and Physical Optics Third Edition

R S Longhurst

This well-established text covers the whole field of modern classical geometrical and physical optics and gives a comprehensive and up-to-date account of the subject. The thorough revision undertaken for this third edition ensures that *Geometrical and Physical Optics* retains its value as an undergraduate text and as a general work of reference in the subject. £3.50 net

The Geography of the Flowering Plants

Fourth Edition

Ronald Good

The fourth edition of Professor Good's well-established book is a major revision made in the light of man's recent increased understanding of the geographical position of the flowering plants. The most far reaching of these developments in the study of plant geography is the acceptance of what has long been called the theory of continental movement. This theory has now become one of the basic principles of geophysics and is adequately covered in this highly authoritative text. £9.00 net

Longman
1724 - 1974

and the final year of degree courses will be grateful to Professor Sheppard and the other contributors for producing this excellent hybrid between text book and practical manual. The seven chapters include full descriptions of the techniques of cytogenetics and the culture methods for a wide range of organisms with detailed practical guides to exercises in basic genetics using *Drosophila*, fungi, bacteria and bacteriophage. Other chapters outline exercises in population, ecological and quantitative genetics and provide clearer accounts of biometrical genetics and elementary statistics than are found in most textbooks. Perhaps the chapter of most general value is the one concerned with higher organisms where a mine of information on the use and availability of teaching material emphasises that practicals in genetics need not be restricted to the few organisms commonly used in research.

Some of the suggested exercises can each be carried out by individuals in a single practical session, whereas others require the cooperative efforts of a number of students over a full term. All of the authors have provided a useful list of altruistic university departments and commercial suppliers that can provide suitable materials.

The editing is lenient, allowing some useful repetition, but the legend to plate 4.7 underlines the role of practicals in encouraging students in critical observation: those who follow the instructions and prepare slides of meiosis in locust species, might question whether the plate depicts diakinesis in *Schistocerca gregaria* or diplotene in some other species. JOHN GIBSON

Protein in stereo

Atlas of Molecular Structures in Biology. 1, Ribonuclease-S. Prepared by F. M. Richards and H. W. Wyckoff; edited by D. C. Phillips and F. M. Richards; figured by J. L. Mouning and J. W. Schilling. Pp ix+75. (Clarendon: Oxford; Oxford University; London, 1973.) £3.50.

PRESENTING the structure of a protein molecule is perhaps as immense a problem as solving the structure. In this volume on ribonuclease-S the editors and authors present a workable format for this task. It is the intention of the series to present structure unencumbered by interpretation. A short description of what the enzyme does, giving appropriate references to more detailed reviews and primary source material, starts the pleasantly brief text. After all, it is the pictures which are important in this book. Following is a series of tables and figures giving such items as physical properties, amino acid

sequences, Cartesian coordinates, hydrogen and ionic bonds, and various contact and angular properties of the chain. Some of the measured coordinates and angles are presented in several different forms, thus eliminating some conversion by the reader and making the work more usable.

The heart of the volume is the computer-generated drawings of the molecule. Forty-three red-green stereo drawings depict the main chain and all non-hydrogen side chain atoms from three mutually perpendicular directions. Four of these are specially devoted to the environment around the UpcA inhibitor complex. Many of the others are taken in ordered slices through the molecule. The publishers did an excellent job in the alignment of the stereo pairs but there was a slight shadow effect caused by an incorrect match of the green ink with the green filter in the stereo glasses provided. This effect became more pronounced as one moved closer to the diagram to read the small residue labels. From normal viewing distance the three-dimensional effect was quite good.

The last section contains the electron density maps for the apo-protein. This section should give the non-crystallographer the opportunity to see how a complete electron density map looks. The electron density of each section of the map is printed in green, and superimposed on it are all the atoms involved in that section with their Van der Waals radii drawn in red. By closing one eye and using the stereo glasses, one can see either the map or model. This section is excellent in its concept and execution. Unfortunately there is no index as to which sections on the map a residue will appear in, so the co-ordinate list must be used.

In general, the volume provides an excellent source for the structure of ribonuclease-S. Distances between residues of interest can easily be calculated from the coordinate lists and environment relationships can be found by consulting the many stereo diagrams. The major fault of the series is not in this volume, but perhaps in future volumes. Ribonuclease-S is approximately one-fifteenth the size of the larger multi-component proteins now being studied. The inclusion of the necessary diagrams to fully depict the subunit structure and the important subunit-interactions of one of these large proteins would not only make the volumes larger, but more expensive to produce and to purchase. Unfortunately, there seems to be no simple solution to the problem of disseminating all the structural information of a molecule as large as a protein, and this volume presents a good compromise solution. STEVEN J. STEINDEL

Muscle and silk

Conformation in Fibrous Proteins and Related Synthetic Polypeptides. By R. D. B. Fraser and T. P. MacRae. Pp. xviii+628. (Molecular Biology: An International Series of Monographs and Textbooks.) (Academic: New York and London, December 1973.) \$45; £19.50.

THE fibrous proteins form an important class among the complex structures found in living organisms, and the investigation of their structure poses special problems because they cannot, in general, be obtained in the form of single crystals suitable for X-ray investigation. The first part of this book describes the major techniques in current use and their application to the problems. They include X-ray, electron and optical diffraction, electron microscopy, infrared spectroscopy (using polarised radiation) and the important if less direct techniques based on the use of known atomic dimensions and interaction energies which may be described as model building. There is also a chapter on methods for obtaining the optimum structure and another on several techniques of more limited application.

The second part describes in considerable detail the several well-characterised conformations found in synthetic polypeptides (α -helix, β -conformation and so on) which have been basic to an understanding of the structure of fibrous proteins, and there are separate chapters on the silks (of which many kinds are known), collagens, muscle proteins and the keratins. There is a chapter on fibrin, fibrinogen, flagellin, elastin and resilin.

The writing is lucid and critical. The many line diagrams are excellent and there is a good selection of half-tone reproductions, chiefly of diffraction patterns and electron micrographs. The list of references is very comprehensive and it is evident that care has been taken with the indexes. The authors (who have made major contributions to our understanding of fibrous protein structure) are to be congratulated on the publication of such a thorough and useful work.

A. ELLIOTT

Drifting in the Pacific

The Settlement of Polynesia: A Computer Simulation. By M. Levison, R. Gerard Ward and J. W. Webb. Pp. vi+137. (University of Minnesota Press: Minneapolis, 1973.) £5.50.

THE question of how the scattered islands of Polynesia were settled during a 2,000-year period ending about a thousand years ago has been a perplexing one for European colonisers

whose own methods of navigation only allowed them to arrive there less than 300 years ago. One rather loud voice in the debate in recent times has been that of Andrew Sharp. He simply applied to the problem his hard-headed common sense, Occam's razor, and a due cynicism about far-fetched or fantastical tales of intrepid ancient Polynesian seamen with sophisticated navigational skills. After all, Polynesians were both illiterate and living in the Stone Age. Sharp's thesis is that island discovery took place by unnavigated one-way voyages either of exile, or accidental drift, and that there is no reason to suppose that deliberately navigated journeys of exploration or long voyages with return to the starting place occurred. In the preface to his 1964 book, Sharp states, "It is six years since my previous book . . . During those years I have gathered upwards of a hundred published notices . . . and have been involved in 2,191 oral discussions of the book's themes. I have yet to hear of a fact or read an argument which impugns the basic contentions of the former book". The present book by Levison, Ward and Webb, contains both facts and arguments which do impugn Sharp's contentions.

What Levison, Ward and Webb have done is to take the recorded data of frequencies of different winds and currents throughout the Pacific, and simulate by computer one-way drift voyages from a variety of starting points.

All the assumptions of the simulation seem remarkably sensible. On each day a particular wind and a current direction are chosen randomly from the available recorded frequencies of winds and currents for the particular month in the particular $5^\circ \times 5^\circ$ (approximately 300 nautical mile) square, and the vessel is moved an appropriate distance and direction. A craft makes a landfall if it passes within 10 miles of a low island or 20 miles of higher ones. There is a sigmoid curve of increasing tendency of a voyage to end due to factors like death of the crew (50% of voyages terminate in this way by 10 weeks). But there is also a 0.5 probability of foundering if a gale of force 9 or above occurs.

The authors have simulated more than 100,000 drift voyages, and 8,000 deliberately guided ones. The drift voyages included a main series of 46,000 from 61 starting points starting every day of the year, 11,000 under shifts of climatic conditions of the kind that might have occurred in the last 2,000 years or so, 32,000 starting from specially advantageous points at specific months of the year, and 10,000 in reverse from destinations towards possible starting points.

Their conclusion was that drifting produced a zero probability of reaching either Hawaii or Easter Island from any inhabited part of Polynesia, and less than 0.1% chance of reaching New Zealand. Thus drifting alone does not seem to be able to account for the colonisation. Among other things they also show that Kon Tiki would never have reached Easter Island, or anywhere else in Polynesia unless it had been very deliberately steered westward (which it was). Indeed, in simulated voyages with an attempt to hold a particular course, and with a limitation of only being able to lay as close as 90° to the wind, the chances of reaching the outlying parts of Polynesia become quite reasonable.

Levison *et al.* are judicious on the subject of relevant archaeological data and the various theories that have been put forward. They also are scrupulous about the technical part of their simulation. Both a complete listing of their ALGOL program and a large selection of their results in the form of maps of scattered destinations of voyages from particular starting places appear in appendices which occupy about half the book. But the non-technical should not be deterred. The text though detailed is well written, and the whole is a substantial contribution. Put together with the recent publications by Gladwin and Lewis of sophisticated navigational techniques still practiced in the Caroline Islands, this work finally disposes of the idea that Polynesians were savages who just happened to have been blown to accidental discovery of the vast reaches of the Pacific which they came to inhabit.

KEITH OATLEY

Relativity with reprints

General Theory of Relativity. By C. W. Kilmister. Pp. ix+365. (Commonwealth and International Library: Selected Readings in Physics.) (Pergamon: Oxford and New York, November 1973.) £3.50 boards; £2 paper.

ACCORDING to the publisher's note on the back cover, this book meets "the increasing need for an undergraduate text on the general theory of relativity". It will be an unusual undergraduate work which absorbs more than a portion of it but there is a need for a textbook for all students with ambitions to research into relativity, cosmology and astrophysics (and pure differential geometry). This should ideally not only present the facts about relativity they need, but also assist the transition from didactically helpful lectures to the scientific literature.

This book is important because it has both these aims. Before venturing

to carp at unimportant idiosyncracies I should say that it is wholly recommended to such students because it largely fulfills them. The first hundred pages contain the author's exposition of the principle of equivalence, of Einstein's theory and of more recent developments. The rest of the book consists of eleven reprinted papers.

The author's account of the motivation for the theory is largely from the equivalence principle. Mach's principle is dealt with summarily; Einstein is said (page 12) to have hoped that his theory would incorporate it but the grounds for this hope are not made clear. Eddington's demonstration that relativity diminishes the number of constraints that "laws of nature" impose on the world is scarcely mentioned though for many students it is the most stimulating feature of the elementary part of the theory. Cosmology is dealt with quite briefly; the Robertson-Walker models are not derived and the book is not advanced enough for global properties or singularity theorems. Gravitational radiation is taken no further than the classic 1962 paper of Bondi, Burg and Metzner which is reprinted with explanation in the text; and the spinor calculus no further than Penrose's 1960 paper reprinted without.

The book is therefore not quite an introduction to current research, but an advanced textbook, and a very good one.

P. E. ROE

Teaching mathematics

Developments in Mathematical Education. Edited by A. G. Howson. Pp. ix+318. Proceedings of the Second International Congress on Mathematical Education, Exeter, UK, August 1972.) (Cambridge University: London, 1973.) £4.80; \$14.50.

THE conference reported by this book consisted of thirty-eight working groups which dealt with the subject, on a broad basis, from kindergarten to the university.

The report appears in three parts. The first consists of a survey of the congress and covers a wide range of topics, including the psychology of mathematics learning; mathematics and language; mathematics at primary and secondary level and its link with other subjects, applications, history and assessment of mathematics; professional training of teachers and the use of teaching aids; and mathematics in developing countries.

The second part of the report consists of invited papers whose authors include G. Pólya, J. Piaget and Sir James Lighthill. There is also a paper by S. L. Sobolev on "Some Questions

of Mathematical Education in the U.S.S.R.". The third part consists of a selection of congress papers. These cover problem solving; intuition, structure and heuristic methods; geometry as a gateway to mathematics; and the work of Piaget in the training of students to teach primary mathematics.

My impression of the present state mathematical education is that too much is going on at the same time on too many fronts. Confusion is evident in the clash of differing philosophies, and it will probably be a matter of decades before a settled place is found for mathematics as a field of human endeavour. There seems to be far too much experiment, much of which is badly planned, or, worse still, introduced on impulse. But mathematical concepts, as a way of thinking, are recognised as being of greater importance than in any past period of history. Mathematics is no longer a matter only of number and numeracy. Structure, including concepts and their relationships, is now consciously identified as a fundamental aspect of human thinking. One of the main problems of mathematical education in the coming years will be to determine the place of structure in the thinking and behaviour of the mass of mankind.

L. S. GODDARD

Air and ocean

The Physics of Air-Sea Interaction. By S. A. Kitaigorodskii. Translated from the Russian. Pp.v+237. (Israel Program for Scientific Translations: Jerusalem, 1973.) n.p.

THIS book will undoubtedly become an essential work for the ever increasing circle of physicists, meteorologists and oceanographers for whom the interaction of the air with sea has become an important problem. Although there are omissions it will provide an up-to-date text upon which to build some of the newest theories of air-sea interaction.

The book is written in three parts. The first part, "Dynamics of the Marine Surface Mixing Layer of the Atmosphere", is devoted to the physics of the layer of the atmosphere immediately adjacent to the water surface. From the starting point of the Monin-Obukhov form for the generalisation of a logarithmic boundary layer to a temperature-stratified medium, the author examines the usual turbulent fluxes of momentum, heat and water vapour before continuing with a study of the aerodynamic drag of the sea surface and its relation to the characteristics of the turbulent atmosphere and of wind-generated waves. Several chapters are devoted to the analysis of results from field measurements of atmospheric

turbulence over waves in the Mediterranean and show some of the procedures used for evaluating the results from this complex problem. The last chapter in part 1 is concerned with the possible influence of high humidity on the vertical density stratification over oceans and collates and analyses data from many sources on gradient measurements and standard seaborne observations.

Part 2, "Wind Waves in Deep Sea" is a description of some fairly general similarity hypotheses concerning wind waves, and of tests of these on experimental data. The author attempts to reduce the complexity of the problem by obtaining some universal dimensionless parameters to describe the relationship between the turbulent wind and the spectrum of the wind waves. The approach and content is very different to that found in Kinsman's *Wind Waves* and these two texts complement each other well. Again there is much use made of experimental data with prominence given to the Soviet Mediterranean expeditions in 1965. Particularly interesting are the results from a wide-band string wave recorder used to obtain extensive measurements of open-sea wave characteristics in the high frequency region (up to 7.5 Hz). No mention is made, other than a statement confirming its omission, of the non-linear interaction between components in the wave spectrum.

In the third part, "Dynamics of Vertical Mixing Processes in the Upper Ocean", the author turns from his extensive use of experimental data and considers some of the many physical hypotheses underlying the characteristics of sea turbulence and the ways in which they effect the vertical mixing processes. Several models are used to make predictions about the energy balance of dynamic small scale turbulence in the wind mixing layer. The final chapter considers the seasonal variations in the active layer of the ocean. It seems a little out of place in a book concerned mainly with the physics of small scale interactions. Perhaps the author is right at this point to expand the field of view and to introduce some long term variations.

The text is also valuable for the attention it pays to some of the less well known expedition results of the Institutes of Atmospheric Physics and Oceanology of the Academy of Sciences of the Soviet Union and for the comparisons made between these data and those of the more usually quoted sources. Overall, an excellent book; my only criticisms are the minute size of type used for the equations and the confusing choice of symbols on a few diagrams.

C. E. VINCENT

science on television

Human face of Watson and Crick

by Peter Newmark

Back in the balmy days of the early 1950s, before the national press was heavy with doom and the scientific press with molecular biology, small groups of scientists in London, Cambridge and California were working away on the academic problem of the structure of DNA. And then it happened. The day after Mr Churchill became Sir Winston, Francis Crick and James Watson published their proposed structure for DNA in these pages and "The Race for the Double Helix" was over. The Horizon programme of that title dealt with the last few months leading up to this discovery.

Treading much the same ground as, and in a similar vein to, Watson's book *The Double Helix*, the programme dealt with the people involved much more than with the science. Indeed the only real bit of experimentation shown, R. G. Gosling trying to stretch a DNA fibre, failed (intentionally?) in front of the camera. What was shown, and very successfully, was the way in which the course of the race was affected by the personalities involved.

The story was narrated by Sir Michael Swann and divided into segments each introduced, silent movie style, with a still caption—such as "The Race Is On". But anyone expecting matching melodrama, villains and chivalrous heroes would have been disappointed. The characters were no larger or better behaved than life. There were Maurice Wilkins and his group studiously improving their X-ray data and moving towards the answer, Linus Pauling applying his expertise to other X-ray photographs and Watson and Crick building models *ad infinitum*.

All these people and more appeared to tell their tale. Of the main characters only Rosalind Franklin is no longer alive. It was her involvement that provided the most human touch to the whole story. Employed by Wilkins for her knowledge of crystallography, it soon became evident that the two were incompatible. This, or so it was related in the programme, resulted in a degree of isolation for Franklin that probably cost her the first place in the race. Nor were relations between her and Watson much better. He needed her data but

could offer little in return. Meetings were tense and even degenerated to fisticuffs on one occasion. Pauling was equally human. Although expecting to discover a double helix, he made a crucial misinterpretation of some data and opted for a triple helix. His son passed a pre-publication copy of the paper describing this to Watson and Crick. Their disbelief in the proposed structure acted as a spur for their own activities.

From their own account, surely a bit exaggerated by the passing of years, theirs was casual labour. Between coffee and tennis, Watson would play with bits of cardboard whilst Crick, trying to complete a mature doctoral thesis, would occasionally add a word of advice. Whatever the truth, and Watson did at one stage admit to working hard, the base pairing was realised and the full structure immediately followed.

Crick has recently written that in their classic paper "the structure is produced like a rabbit out of a hat, with no indication as to how we arrived at it." The nice thing about the programme was that it did show how, and in human, rather than scientific, terms. It was an excellent exercise in demonstrating the foibles and failings of scientists and acted as a splendid counterbalance to the reverent attitudes to which even Horizon is often prone. Nevertheless it was made quite clear that some three months before Mount Everest was first climbed, a scientific discovery of equal magnitude had been achieved.

The Valley of Paradise

by Allan Piper

LIKE Liverpool versus Leeds, and Royal Weddings, Vilcabamba—the "Valley of Paradise"—and its extraordinary inhabitants might have been made for television. In a beautiful, sun-filled bowl, 6,000 feet up in the Ecuadorian Andes, a community of gentle peasants farm the fertile land. Amazingly, in spite of a daily consumption of 40 cigarettes, four cups of locally distilled, 110° proof rum, and the occasional guinea pig, many of these strange people live to ages of more than 120 yr. And as if that were not enough to ensure a captive audience, there is a hint that it could be attributable to a healthy

sex life. But disappointingly, and uncharacteristically, Granada's "World in Action" team never quite made the best of what was bound to be a good documentary.

Arriving just ahead of the new road through the mountains, and the inevitable tourists, the camera crews have been beaten to Vilcabamba only by the scientists.

Many of their theories are predictable: "The air is so pure" and so on. Other theories are more unorthodox and intriguing. It has been suggested that centuries of close inbreeding have isolated a genetic abnormality, or more remarkable, that after a lifetime of climbing steep slopes and working the land, the calf muscles of these people have become so powerful that they operate as a secondary heart. But the inhabitants of Vilcabamba pay a price for their longevity: half of the children of the valley die before they are 10.

In spite of its unusual content, however, the documentary, (screened on July 8) lacked a sense of coherence. It was never cogent or compelling. Perhaps that was because "World in Action" tried to do too much in too little time. As a result, the programme was often vague and contradictory. We were told that, for example, all the peasants are vegetarian, and also that some eat donkey meat.

We were also presented with various nuggets of hollow information: There are two rivers flowing through Vilcabamba. One is warm, the other is cold. Ho hum. And we were treated on the basis of slender evidence to the thesis that an older woman might be so old because of her healthy attitude towards sex. "Did you have many lovers?" she was asked. Well, she was married once but her husband died a long time ago; just as well really, he used to be a devil—always beating her. Nearly killed her once. Eeee.

Miguel Carpio, 132 years old, tall and bronzed with long black hair and a snow white beard, retired from a life of farming at 125. Healthy and in command of all his mental faculties, he sits upright and impassive as the young intruders from the outside world try to come to terms with his only obvious handicap. "Do you", bawls the reporter, an impolite six inches from Miguel's left ear, "still like women?" Obviously, Miguel is going deaf. Probably, it doesn't bother him very much: at his age he's undoubtedly heard it all before.

Science broadcasting statistics

The proportion of BBC radio time spent on science has never been lower, in spite of the fact that the proportion of time devoted to talks and discussions has been increasing over the past ten years. Yet television has shown that there is a market for science, with ten million viewers watching *The Burke Special*.

James Friday, an archivist on the staff of the Royal Institution has been collecting statistics on the BBC's use of programme time. In 1923 Reith, with his brief to educate, inform and entertain devoted $\frac{1}{2}\%$ of radio time to

scientific programmes. Subsequently the emphasis shifted heavily to entertainment and science was relegated to schools programmes. In 1943 with science up to about 1%, the British Association, whose general secretary was then Richard Gregory, editor of *Nature*, sent a delegation to the BBC to suggest improvements in science broadcasting. The delegation recommended that the BBC should appoint a scientific advisory group and a scientific programme organiser. The BBC rejected both proposals. When similar proposals were made twenty years later by the Pilkington Commission they were accepted in part: a Science Consultative Group was appointed in 1964. But, its influence seems to have been negligible.

Television science has clearly not suffered from the BBC's dislike of having scientists in its midst. But radio producers seem to have become progressively more intimidated by the subject: science at present occupies $\frac{1}{4}\%$ of BBC radio time. With television science included, the proportion rises to slightly over 1%—little more than in 1943. Yet surely science impinges on most peoples' lives considerably more than it did in 1943? The BBC—and scientists—should consider, said Friday in a recent RI lecture, how they can best transmit science and how many hours a week they need to do it before they are overtaken by the report of the Annan Commission and the timidity of the programme producers.

Announcements

Appointments

Roy Gibson has been appointed Acting Director General of The Council of the European Space Research Organisation.

Erratum

In the article 'Nuclear fission as a general source of energy' by L. R. Shepherd (*Nature*, **249**, 717; 1974) the two figures were inadvertently printed above the wrong figure legends. The legends themselves are correct and in the right places.

International meetings

September 2–6, **International Symposium on Approaches to the Early Detection of Chemical Toxicity**, Guildford (Mrs J. King, Department of Biochemistry, University of Surrey, Guildford GU2 5XH).

October, **International Symposium on Andean and Antarctic Volcanology Problems**, Chile (Professor O. Gonzales-Ferran, Department of Geology, University of Chile, Casilla 13518, Correo 21, Santiago, Chile).

October 6–11 **Symposium of the International Society for Photogrammetry**, Banff, Canada (Dr L. Sayn-Wittgenstein, Canadian Forestry Service, Ottawa, Canada).

October 7–11, **First World Congress of Genetics Applied to Animal Production**, Madrid (Professor Dr Luis de Cuenca, Fac de Vet, University of Madrid, Ciudad University, Madrid, Spain).

October 10–12, **International Symposium on Thermogenesis and Depressed Metabolism**, Czechoslovakia (J. Meisner, MD, CSc, General Secretary, Faculty of Natural Sciences, Vinicna 7, 120 00 Praha 2, Czechoslovakia).

October 13–16, **Symposium on Temperature Regulation**, Israel (The Secretariat, POB 983, Jerusalem, Israel).

October 13–16, **Symposium on the Mechanisms of Synaptic Action**, Israel (The Secretariat, POB 983, Jerusalem, Israel).

October 13–17, **Symposium on Environmental Physiology** (The Secretariat, POB 983, Jerusalem, Israel).

October 13–19, **Fifth World Congress of Gastroenterology**, Mexico (V Congreso Mundial de Gastroenterología, Avenida Veracruz 93, Mexico 11 DF, Mexico).

October 14–18, **International Symposium on the Regulation of Growth and Differentiated Functions in Eukaryote Cells**, New Delhi (Professor G. P. Talwar, Department of Biochemistry, All India Institute of Medical Sciences, New Delhi, 11016, India).

October 20–22, **Sixth Meeting of the International Association for the Study of the Liver**, Acapulco (VI Reunion de la Asociacion Internacional para el Estudio del Higado, Avenida Veracruz 93, Mexico 11 DF, Mexico).

October 21–23, **3rd Conference on Application of Small Accelerators**, Texas (Dr Jerome L. Duggan, Department of Physics, N. Texas State University, Denton Texas 76203).

October 21–25, **Symposium of the International Atomic Energy Agency on the Thermodynamics of Nuclear Materials**, Vienna (International Atomic Energy Agency, PO Box 590, A-1011 Vienna, Austria).

October 21–25, **Second Conference of the Condensed Matter Division of the European Physical Society**, Budapest (EPS Condensed Matter Division, Conference Office, Research Institute for Technical Physics, 1325 Budapest, PO Box 76, Hungary).

The Publishers will not be liable for any loss occasioned by the failure of any advertisement to appear from any cause whatever, nor do they accept liability for printers' errors, although every care is taken to avoid mistakes.

Semi-displayed £3.60 per 10 mm. Minimum £7.20, each additional 2 mm 72p. Full page £230.00. Half page across £125.00. 30p is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, London, WC2A 2ED. Telephone: 01-242 6264. Telegrams: Textualist, London, W.C.2.

APPOINTMENTS VACANT
**UNIVERSITY OF ALBERTA
DEPARTMENT OF ENTOMOLOGY**

Applications are invited for the position of **ASSISTANT PROFESSOR**, effective April 1, 1975. Qualifications are Ph.D. with postdoctoral experience in insect physiology and interest in aspects of this field applicable to agricultural or forest entomology. Duties include teaching courses in general or applied entomology and insect physiology, the development and direction of a research program and supervision of graduate students in insect physiology and in application of some aspect of physiology to agricultural or forest entomology. Maximum starting salary \$14,043.

Please send full curriculum vitae and names of 3 referees by October 31, 1974 to: Dr George E. Ball, Chairman, Department of Entomology, 260 Agriculture Building, University of Alberta, Edmonton, Alberta T6G 2E3. (297)

UNIVERSITY COLLEGE GALWAY
**JUNIOR LECTURESHIP
IN ZOOLOGY**

Applications are invited for the above post. Salary scale £2,478 by 99 (10) to £3,468, plus Family Allowances. The closing date for receipt of applications is **August 8, 1974**. Prior to application, further information should be obtained from the Registrar of the College. (308)

**CHARING CROSS HOSPITAL
MEDICAL SCHOOL**

Applications are invited from persons with some experience of electron microscopy or graduates considering entering this field for a new appointment of technician in the Department of Histopathology of Charing Cross Hospital Medical School. Duties commencing September/October 1974 will include the maintenance and operation of transmission and scanning electron microscopes. Some initial training will be given which the successful applicant will be encouraged to supplement by external study. Whitley Council terms and conditions of service. Apply to Dr J. G. Jackson, Department of Histopathology, Charing Cross Hospital Medical School, Brandenburgh House, Fulham Palace Road, London W6 9HH. (352)

**THE UNIVERSITY OF SHEFFIELD
W.E.S. TURNER CHAIR OF
GLASS TECHNOLOGY**

Applications are invited for the **W.E.S. TURNER CHAIR OF GLASS TECHNOLOGY** which will become vacant in September 1975 on the retirement of Professor R. W. Douglas. Salary in the range approved for professorial appointments with superannuation provision. Further particulars may be obtained from the Registrar and Secretary, The University, Sheffield S10 2TN to whom applications (one copy only) should be sent by September 21, 1974. Please quote reference R116/G. (384)

**SOUTH AFRICAN SUGAR ASSOCIATION
EXPERIMENT STATION
MOUNT EDGECOMBE, NATAL
REPUBLIC OF SOUTH AFRICA**

CHIEF RESEARCH OFFICER

The Experiment Station of the South African Sugar Association at Mount Edgecombe, Natal, requires the services of a Chief Research Officer. The successful applicant will be responsible to the Director for the operations of the following departments: Agricultural Engineering; Agronomy; Biometry; Chemistry and Soils; Entomology and Nematology; and Land and Water Management. His duties will include the preparation and supervision of annual programmes of work, the administration of a specialist advisory service to all sugarcane growers and the motivation and co-ordination of special research projects. Applicants should preferably hold a Ph.D. or an equivalent degree in science or agriculture. Extensive experience in research will be an essential pre-requisite.

This appointment holds good prospects for an outstanding scientist with organizing ability. It will also include opportunities for overseas travel when visits to other institutes are warranted.

Salary will be commensurate with qualifications, experience and the senior grading of the appointment.

Application forms, a list of benefits (which include a 10% annual bonus) and conditions of service are obtainable from:

**South African Sugar Association,
Fountain House,
125-135 Fenchurch Street,
London,
England EC3M 5EH.**

Completed forms, together with curriculum vitae, should be air-mailed directly to:

**The Director,
S.A.S.A. Experiment Station,
P.O. Mount Edgecombe, 4300,
Natal,
Republic of South Africa.**

(332)

Pharmacologists

The Union International Company Ltd., invites applications for two new posts in the Department of Pharmacology at the St. Albans Research Centre:—

- (A) will be involved with work on mitotic inhibitors, malignancies and immuno-suppression.
- (B) will be involved mainly with various aspects of biological Quality Control work, though there will be opportunities in several of the Department's research projects.

Applications for both posts must have an Honours Degree in Pharmacology, Pharmacy or other appropriate discipline.

Please write, giving full personal, educational and career details to the Staff Manager, (AD 5835), Union International Company Ltd., 14 West Smithfield, London EC1A 9JN.

(428)

British Museum (Natural History)
Sub-department of Anthropology

SCIENTIST

to assist in experimental and bibliographic research in the fields of biometry, radiometry and serology. The work involves the anthropometric and anthroposcopic study of skeletal material in the Museum collection, and investigation of physical and genetic characters in contemporary populations. The successful candidate will also undertake some curatorial duties.

Candidates (aged under 27) must

have a degree, HNC or equivalent in an appropriate subject.

Appointment will be as Scientific Officer; salary in the range £1,900-£3,000.

Application forms (to be returned by 16 August 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service). Please quote SB/32/DK. (382)

COLAISTE NA hOLLSCOILE GAILLIMH (UNIVERSITY COLLEGE GALWAY, IRELAND)

Department of Physics

Applications are invited for a

POST-DOCTORAL FELLOWSHIP

to investigate the heterogeneous nucleation of the solid phase, and its application to:

- deliberate and inadvertent weather modification
- Measurement of the concentration of lead-bearing particles in the atmosphere.

The successful candidate will probably have a Ph.D. in Physics, Chemistry or Meteorology.

The Fellowship will be supported by the National Science Council of Ireland. The appointment will initially be for one year, from October 1st, 1974, with a possible renewal for one or two further years.

Salary will commence at £2,100 per annum.

Applications, accompanied by a curriculum vitae, and the names of two referees, should be sent to—

Dr. A. F. Roddy, Department of Physics, University College, Galway, Ireland, from who further details are available.

Closing date is August 6th, 1974.

(398)

CITY OF LONDON POLYTECHNIC

Applications are invited for a research assistantship (£1,544 to £1,654 per annum, plus payments under Threshold Agreement) to work on the biochemistry of parasitic castration in the roach by the tapeworm *Ligula intestinalis*. The post is tenable for three years and the successful candidate will be expected to register for a higher degree.

Application forms and further details can be obtained from Dr. G. L. Underwood, Department of Biological Sciences, City of London Polytechnic, 31 Jewry Street, London EC3N 2ET.

Closing date—September 16, 1974.

(434)

THE UNIVERSITY OF MANCHESTER Institute of Science and Technology DEPARTMENT OF CHEMISTRY

Experimental Officer (Ref: C/108/AI)

Applications are invited for the post of Experimental Officer in the Department of Chemistry to take responsibility for the running of an Electron Spin Resonance Spectrometer.

The instrument is to be used to provide an analytical service to research and teaching groups in the department and also to carry out development work in the use of E.S.R. and its application to departmental projects.

The post will be particularly attractive to candidates combining a chemical background with an interest and practical knowledge in electronics.

Salary within the scale: £1,758 to £3,114 with F.S.S.U.

Requests for application forms to the Registrar, U.M.I.S.T. Sackville Street, Manchester M60 1QD, to be returned not later than August 6, 1974.

(385)

UNIVERSITY OF EAST ANGLIA SENIOR DEMONSTRATORSHIP IN CHEMICAL PHYSICS

tenable for 2 years from October 1, 1974. Some preference will be given to candidates who have interests in surface chemistry. Salary within the range £2,118 to £2,931 p.a. depending on qualifications and experience, plus F.S.S.U. benefits. Applications should be submitted as soon as possible to Professor N. Sheppard, F.R.S., School of Chemical Sciences, University Plain, Norwich, NOR 88C.

(386)

JUNIOR TECHNICAL OFFICER

required at Institute of Cancer Research, Fulham Road, London SW3, to work in the Division of Molecular Biology. The work is concerned with the isolation and characterisation of proteins in relation to cancer. Candidates should have at least two 'A' levels passes in Chemistry, Physics, Mathematics or Biology. Salary in scale £1,173 to £2,073, plus London Allowance and threshold awards.

Apply in duplicate with the names of two referees, to the Secretary, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/527.

(387)

UNIVERSITY OF NEW SOUTH WALES PROFESSOR of PURE MATHEMATICS

Applications are invited for appointment to a chair of pure mathematics in the School of Mathematics; there are five chairs in the School, including another one in pure mathematics. Applicants should have substantial research interests in some branch of pure mathematics. The new professor will supervise and participate in teaching and examining undergraduate and postgraduate students in the School and engage in and promote research and advanced study in the field of his chair.

Salary, \$A19,614 per annum. Subject to the consent of the University Council, professors may undertake a limited amount of higher consultative work. The University reserves the right to fill any chair by invitation.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on September 30, 1974.

(392)

UNIVERSITY OF NEW ENGLAND ARMIDALE, NEW SOUTH WALES TEMPORARY LECTURESHIP — AGRICULTURAL BIOLOGY (12 Months)

Applications are invited from graduates in Agriculture, Biology, or Veterinary Science with a particular knowledge of host parasite relationships, epidemiology of livestock parasitic disease and integrated management control measures in agricultural enterprises. Ideally applicants will be familiar with and experienced in student directed learning, the group learning environment and enquiry projects. The appointee will be expected to work in co-operation with a senior lecturer in Pathology and Preventive Medicine to maintain a resourceful learning environment for third and fourth year students of the Faculty of Rural Science in a co-ordinated study of the expressions of disease by livestock through interaction with infective agents; the consequential effects upon productivity; and the means of controlling these with bio-economic constraints by integrated whole enterprise management.

Salary: \$A9,002 to \$A12,352.

Further information can be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on September 6, 1974.

(393)

**UNIVERSITY OF EAST ANGLIA
DEMONSTRATORSHIP
In INORGANIC and/or
PHYSICAL CHEMISTRY**

tenable for 1 year from October 1, 1974. Salary up to a maximum of £2,118 depending on qualifications and experience. Applications should be submitted as soon as possible to the Dean of the School of Chemical Sciences, Professor S.F.A. Kettle, University Plain, Norwich, NOR 88C. (388)

**MEDICAL LABORATORY
TECHNICIAN**

required for expanding diagnostic radioimmunoassay/saturation assay department. Experience in radioisotopic methods is desirable though not essential, but attention to detail and a high standard of orderliness in laboratory work are very important requirements. Successful candidates will be expected to display initiative and to contribute to the development of new techniques in this expanding and important field. Salary on Whitley Council scale according to age and experience (maximum £2,577 p.a.). Applications including a curriculum vitae and the names and addresses of two referees should be submitted to: Professor R. P. Ekins (N), Department of Nuclear Medicine, The Middlesex Hospital Medical School, London WIN 7RL by July 31, 1974. (396)

**THE POLYTECHNIC
OF NORTH LONDON
DEPARTMENT OF CHEMISTRY**

**SRC RESEARCH
TECHNICIAN**

Applications are invited for an S.R.C. research position in each of the following areas:

- Nmr investigations of organothallium compounds. Apply to Dr R. W. Matthews.
- The study of 'template synthesis' and catalysis by transition metal ions. Apply to Dr P. A. Tasker.

The appointments will be made for two years only with salary in the range £1,824 to £2,094. Applicants for either position should be chemistry graduates or have experience in synthetic chemistry and should write as soon as possible, giving details of qualifications and experience, with the names of two referees, to the above at the Department of Chemistry, The Polytechnic of North London, Halloway, London, N7 8DB. (383)

**GRIFFITH UNIVERSITY
Brisbane, Australia
SCHOOL OF SCIENCE
CHAIR IN BIOCHEMISTRY**

Griffith University will start undergraduate teaching in March 1975. The academic organisation is on a broad school of study basis and there is a commitment to interdisciplinary teaching.

Applications are now invited from men and women for the third chair in the School of Science, the existing one being in chemistry and in physics. Some preference will be given to a person with interests in the Biochemistry of metabolism or in physiological chemistry, but candidates with other interests will be considered. The appointment will be from January 1, 1976. In order that the appointee can participate in planning, selection will be completed by April 1975.

Salary will be \$A19,614 p.a. Rates of exchange as at June 1, 1974 are: \$A1=UK 62p, \$US 1.48.

Prospective applicants may care to note that the Chairman of the School of Science, Professor R. D. Guthrie, will be available for consultation in London at the offices of the Association of Commonwealth Universities from July 29 to August 2.

For further information and for details of the method application, please write to the Assistant Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The closing date is September 21, 1974. (394)

**Fonction publique
Canada**

**Public Service
Canada**

**THIS COMPETITION IS OPEN TO BOTH MEN AND WOMEN
SYSTEMS RESEARCH OFFICERS**

Ecological Systems Research Division
Planning and Finance Branch
Environment Canada
Hull, Quebec
\$16,958 to \$22,880

DUTIES: To conduct research on a variety of subjects of national and international interest to develop environmental policies and programs. Current research programs include work on carrying capacity of Canada in terms of population, resources and environment, development of techniques to evaluate environmental intangibles, macro global modelling, the growth ethics and use of systems analysis to develop resources and environmental policies.

QUALIFICATIONS: At least a Master's degree in Economics or in a discipline related to the duties of the position, combined with adequate knowledge and experience in economic theory and analysis.

The knowledge of the English language is essential for these positions.

Please quote reference number: 74-430-20.

Forward resumé or "Application for Employment" (Form PSC 367-401) available at Post Offices, Canada Manpower Centres and offices of the Public Service Commission of Canada to:

E. S. GROUP
SOCIAL-ECONOMIC PROGRAM
PUBLIC SERVICE COMMISSION OF CANADA
TOWER "A" PLACE DE VILLE
OTTAWA, ONTARIO K1A 0M7.

Appointments as a result of this competition are subject to the provisions of the Public Service Employment Act. (389)

HAZLETON LABORATORIES EUROPE LIMITED

Director of Drug Safety Evaluation

H.L.E. has now set up its contract research organisation in the former Tobacco Research Council Laboratories at Harrogate. We are seeking to make key appointments in the Division of Drug Safety Evaluation, which comprises a Department of Toxicology and a Department of Pathology. In particular we are looking for a Director for the Division, whose responsibilities will include the development of the existing facilities for the full range of toxicological investigations required by current legislation.

Enquiries are invited from either Toxicologists or Pathologists who are experienced in the organisation, performance, evaluation and reporting of toxicology studies. Familiarity with the requirements of the C.S.M., F.D.A., etc. is essential and a knowledge of the contract research industry is desirable.

An excellent salary and the usual fringe benefits will be offered to the successful candidates.

Your application and Curriculum Vitae should be sent, in confidence, to the Personnel Officer, Hazleton Laboratories Europe Limited, Otley Road, Harrogate, HG3 1PY. (402)

AGRICULTURAL RESEARCH COUNCIL OF MALAWI

PATHOLOGIST

A vacancy exists in the Grain Legume Productivity Research Unit for a pathologist to develop improved methods of controlling groundnut diseases, especially of *Cercospora* leaf spot and fungi affecting kernel quality. The successful applicant will work in close association with the plant breeder and agronomist.

Applicants should possess a good degree in agriculture, agricultural botany or a related subject with specialist training in plant pathology. A practical knowledge of fungicide dusting and spraying techniques would be an advantage.

The appointment will be for a contract of three years at a salary and overseas allowance commensurate with qualifications and experience. A tax free gratuity of 25% is payable on completion of contract. Generous leave, free family passages, medical and educational allowances and free educational passages are provided together with a furnished house at low rental.

Applications, including curriculum vitae and names of two referees should be addressed to:

Administrative Officer, P/Bag 3, Thondwe, Malawi. (442)

Wellcome

Information Scientist

New Appointment

The Wellcome Foundation is an international research based company manufacturing and selling human and veterinary medicines, vaccines and drugs.

Through the continuous growth of our operations we need to increase the staff of our Clinical Information Department, by appointing an assistant to our Senior Information Scientist. We require a scientist with a M.Sc (Information Science) or postgraduate Diploma in Information Science, or an equivalent qualification. Some practical experience with computerised information retrieval systems would be an advantage. He will assist in the development and maintenance of computerised information storage and retrieval systems and the dissemination of information on a world wide basis. Initially the post will be based at our head office at Euston, London but the Department will move to Beckenham, Kent in three years time.

This is a good opportunity to join a major international company offering excellent terms and conditions of employment including assistance with relocation expenses where appropriate.

Please write quoting reference U/138 to:

Group Personnel,
The Wellcome Foundation Ltd,
183 Euston Road, London NW1 2BP.

(452)

SIMON FRASER UNIVERSITY British Columbia, Canada DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for the position of Assistant Professor.

Qualifications: Ph.D. with postdoctoral experience; a strong mathematical background and research interests in benthic marine communities.

Nature of duties: Teaching undergraduate courses in invertebrate biology and marine ecology; the development of an active research programme.

Salary: Negotiable.

Letters of application, including curriculum vitae and the names and addresses of three referees should be sent to Dr J. M. Webster, Chairman, Department of Biological Sciences, Simon Fraser University, Burnaby, B. C. V5A 1S6, Canada, before October 1, 1974. (403)

University of New South Wales WOLLONGONG UNIVERSITY

to become the

UNIVERSITY OF WOLLONGONG
1st January, 1975

LECTURER IN BIOLOGY (2 positions)

The appointees will be expected to help in the development of a course in biological energetics. One lecturer will be responsible for an instructional unit in biophysics with emphasis on cellular energy relations. The other lecturer will be responsible for an instructional unit in the physiology of multicellular organisms, again with emphasis on their energy relations.

Further information may be obtained from Dr. A. D. Brown, School of Microbiology, University of New South Wales, P.O. Box 1, Kensington, N.S.W. 2033, Australia.

LECTURERS (2 positions) DEPARTMENT OF ELECTRICAL ENGINEERING

Applicants should have high academic qualifications together with research or industrial experience in one or more of the following general areas: electronic circuits, devices and systems generally, logical design and digital techniques; computer engineering and applications; applications of modern control theory; materials science; communications.

Further information is available from Professor B. H. Smith, Department of Electrical Engineering, Wollongong University College, Box 1144, P.O., Wollongong, N.S.W. 2500, Australia.

Commencing salary for both posts according to qualifications and experience within the range \$A9,002 to \$A12,352 per annum.

Conditions of appointment and application forms available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close September 2, 1974. (395)

UNIVERSITY OF GLASGOW LECTURESHIPS IN BIOCHEMISTRY

Applications are invited for two Lectureships in the Department of Biochemistry. The salary will be within the range £2,118 to £3,285 per annum of the new Lecturers' scale of £2,118 to £4,896 per annum, which will be effective from October 1, 1974. Initial placement will be according to qualifications and experience. F.S.S.U.

Applications (eight copies) should be lodged not later than September 6, 1974, with the undersigned, from whom further particulars may be obtained. In reply please quote Ref. No. 3512M. Robert T. Hutcheson, Secretary of the University Court. (397)

Senior Biochemist

A leading British pharmaceutical Research Organisation has a vacancy for a SENIOR BIOCHEMIST to initiate and direct research projects in the areas of pharmacokinetics, drug metabolism, molecular pharmacology and enzymology in association with the design and development of new medicines. Persons with appropriate experience are invited to apply in writing for an Application Form from The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB, marking the envelope CONFIDENTIAL. (405)

Pharmacologists

Bayer AG., one of the world's largest research orientated companies, wishes to recruit additional pharmacologists to work in Germany. Bayer's pharmaceutical research is carried out in a new £8 million research centre in Wuppertal near Düsseldorf. The successful applicants will either be involved in work on the pharmacology and biochemistry of the cardiovascular system or of blood clotting. Experience in these fields would be an advantage, but new graduates (M.D., Ph.D. or comparable degree required) are invited to apply. A knowledge of German is not essential.

The position will be permanent and offers an attractive and competitive salary. There is an annual bonus with yearly salary-related increments and an excellent group pension scheme. All relocation expenses will be paid.

Please apply in the first instance to:
Dr. H. B. Allen,
Medical Director,
Bayer U.K. Limited,
Pharmaceutical Division,
Haywards Heath, West Sussex.

Bayer

(420)

**ROYAL FREE HOSPITAL
SCHOOL OF MEDICINE
DEPARTMENT OF BIOCHEMISTRY
AND CHEMISTRY**

Applications are invited from graduates, or others with suitable qualifications in biochemistry or related subjects, for the post of Research Technician to work on membrane biochemistry for 14 months from September 1, 1974 (S.R.C. Grant). Salary according to age and qualifications up to £1,833 p.a. plus £126 London Allowance and Threshold Payments. Applicants should send a curriculum vitae and the names of two referees, as soon as possible, to Professor J. A. Lucy, Royal Free Hospital School of Medicine, 8 Hunter Street, London, WC1N 1BP (Telephone 01-837 5385). (401)

**Pharmacologists/
Toxicologists**

Honours Graduates, some experience an advantage, required for pharmacological research and short and long term toxicological studies of compounds of potential therapeutic importance. Excellent opportunities for advancement in modern, well-equipped laboratory. Pension and Assurance Scheme. Application Forms from the Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (406)

**M.R.C. CLINICAL RESEARCH
CENTRE**

(Northwick Park Hospital), Watford Road,
Harrow, Middlesex, HA1 3UJ

SCIENTIST to work in CYTOGENETICS

with a team investigating factors in gametogenesis and early mammalian development that might lead to chromosomal abnormality. The successful applicant will work under the direction of Dr C. E. Ford of the Sir William Dunn School of Pathology, Oxford, with Dr R. D. Barnes in the Department of Infant Development at the Clinical Research Centre. Candidates should have experience in cytogenetics and preferably a Ph.D. in this subject.

Salary and conditions of appointment according to age and experience.

Application forms and further details may be obtained from Mrs J. Tucker-Bull.

Please quote ref. 119/1/EB6. (404)

**HISTOLOGY
TECHNICIAN**

required for Pharmacological and Toxicological Laboratory. Experience essential in the preparation and processing of animal tissues. Good working conditions. Pension and Assurance Scheme. Application forms from The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (407)

**NATIONAL VEGETABLE RESEARCH
STATION**

PLANT PATHOLOGIST

There is a vacancy for an officer to assist with research on vegetable virus diseases. Appointment will be as a Scientific Officer (£1,702-£2,675) or Higher Scientific Officer (£2,461 to £3,371), grade and starting salary being determined according to qualifications and experience. Superannuation scheme with allowance to offset personal contributions. The minimum qualification is a degree (or equivalent) in Botany, or horticultural or agricultural science. Candidates for appointment as H.S.O. will normally be expected to have at least five years' postgraduate experience, including experience in plant virus techniques; training in such work will however be given to a less-experienced appointee. Full particulars and application form (to be returned by August 22, 1974) from the Secretary, N.V.R.S., Wellesbourne, Warwick CV35 9EF. (417)

Wellcome

**Senior Biochemist
Enzymology**

The Department of Biophysics and Biochemistry at The Wellcome Research Laboratories, part of the multi-million international Wellcome Organisation, requires a Senior Biochemist to collaborate with a small inter-disciplinary group, who are studying the ways in which drugs react with enzymes.

Candidates should have had several years practical post-doctoral experience in enzymology, and will be able to interpret their results in line with modern biochemical concepts.

The Laboratories are located in beautiful parkland surroundings at Beckenham in Kent, near attractive residential areas and yet within easy reach of London.

Salary and conditions of employment are attractive, including generous assistance with relocation expenses, where appropriate.

Please write, with brief career details, to the
**Personnel Manager,
THE WELLCOME RESEARCH LABORATORIES,
Langley Court,
Beckenham, Kent, BR3 3BS.**

(464)

GREATER GLASGOW HEALTH BOARD—WESTERN DISTRICT

Research Assistant in Renal Transplantation in the Western Infirmary

Salary Scale £1,497-£2,259 (Honours Graduates commence at £1,797).

Applications are invited from Science Graduates for the above post. The work will involve the setting up and supervision of immunological tests used in patients who have undergone kidney transplants. No special experience in this field is required but some training in immunology would be an advantage.

Further details can be obtained from Dr. J. D. Briggs, Renal Unit, Western Infirmary, Glasgow, G11 6NT.

Applications should be addressed to Dr. I. Macleod, District Medical Officer, Greater Glasgow Health Board—Western District, Western Infirmary, Glasgow, G11 6NT, not later than 15th September, 1974. (424)

**UNIVERSITY OF HOHENHEIM (LH)
GERMANY**

Institute of Plant Pathology

The post of a Wissenschaftlicher Rat and Professor (AH 2/3) for "Plant Virology and Bacteriology" is to be filled. The main field shall be virology; the problems of practical plant protection in this field are also to be considered. Experiences in the Tropics and Subtropics are desired.

Applications including a list of publications and curriculum vitae should be sent by September 30, 1974, or as soon as possible thereafter, to:

Dekan
des Fachbereichs Agrarbiologie
der Universität Hohenheim
D-7000 Stuttgart 70
Postfach 106
W. Germany

(433)

HILL FARMING RESEARCH ORGANISATION

PLANTS AND SOILS DEPARTMENT

Applications are invited for a SCIENTIFIC OFFICER to join a team studying the nutritional problems of grasses and white clover growing in hill soils with the objective of improving pasture production.

Minimum qualifications: A pass Degree or Higher National Certificate in Botany or an Agricultural Science subject.

Salary depending on qualifications and experience in scale £1,592 to £2,675 with a superannuation scheme which attracts a 5½% non-pensionable allowance to offset personal contribution.

Further particulars and application form may be obtained from the Secretary, H.F.R.O., Bush Estate, Penicuik, Midlothian. Closing date August 21, 1974. Please quote ref: A/6/192. (480)

Nicholas

Pharmaceuticals, Toiletries
Hospital Supplies

Section Head anti-inflammatory research

The pharmacology department of the research division is expanding and an experienced scientist is required to take charge of the existing anti-inflammatory section. The work entails the direction and conduct of the current biological research programme, research into fundamental aspects of inflammation and the development of new testing procedures.

Applicants should be graduates in pharmacology or a closely related discipline with a Ph.D. and several years post-graduate experience in the inflammatory field.

A good salary is offered and will depend on qualifications and experience.

Publications and attendance at scientific meetings are encouraged.

Benefits include a contributory pension scheme with free life insurance, four weeks holiday and assistance with re-location expenses.

Applications in writing to:
A. J. Strathdee,
Personnel Operations Manager,
Nicholas Laboratories Ltd.,
225 Bath Road, Slough. Berks. SL1 4AU.

(471)

AGRICULTURAL RESEARCH COUNCIL OF MALAWI AGRONOMIST

A vacancy exists in the Grain Legume Productivity Research Unit for an energetic and practical agronomist to conduct a research programme on groundnuts. The successful applicant will work in close association with the plant breeder and pathologist and undertake a study of the fertilizer requirements of groundnuts and the influence of improved varieties and disease control methods on cultural practices. He will also be required to assist with the development and evaluation of harvesting methods.

Applicants should possess a good degree in agriculture, agricultural botany or a related subject. Experience of tropical agriculture would be an advantage.

The appointment will be for a contract of three years at a salary and overseas allowance commensurate with qualifications and experience. A tax free gratuity of 25% is payable on completion of contract. Generous leave, free family passages, medical and educational allowances and free educational passages are provided together with a furnished house at low rental.

Applications including curriculum vitae and names of two referees should be addressed to:

Administrative Officer, P/Bag 3, Thondwe, Malawi.

(443)

UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS

Applications are invited for the post of Post Doctoral Senior Research Assistant from October 1, 1974. The successful candidate will be expected to pursue research in Cosmic Ray Physics involving calculations of the night sky Cerenkov radiation and measurements at the Mount Hopkins Observatory of the Smithsonian Institution, Tucson, New Mexico. The periods of work in the United States will be for up to 12 months.

The appointment, which is funded by the Science Research Council, will be for a period of two years.

The salary will be on the scale £2,055 to £2,793 with F.S.S.U. benefits.

Applications (3 copies) including the names and addresses of three referees should be sent to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.

Closing date August 15, 1974.

(411)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF OPERATIVE DENTAL SURGERY

SENIOR RESEARCH ASSOCIATE

Applications are invited for a postdoctoral post as Senior Research Associate to work on research into the chemical characterisation of bioadhesive secretions in the common sea mussel in collaboration with Mr. M. Cook and Dr. P. W. Kent in the Universities of Newcastle upon Tyne and Durham. The research which is supported by an M.R.C. grant will be carried out at the Dental School, Newcastle upon Tyne, and the appointment will be for a period of up to three years from October 1, 1974. Commencing salary up to £3,108 per annum with F.S.S.U. Applicants should have had experience in biochemistry or relevant chemistry of natural products.

Applications giving the names of two referees should be sent to Mr. M. Cook, the Dental School, Northumberland Road, Newcastle upon Tyne, NE1 8TA within three weeks of this advertisement.

(415)

UNIVERSITY OF STERLING DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH FELLOWSHIPS

Applications are invited for Postdoctoral Research Fellowships for work on (a) The Biosynthesis of a fungal antibiotics and (b) In Vitro Analogies for the Biosynthesis of certain Terpenes.

The appointments would be for one year in the first instance, commencing October 1, 1974. Salary will be on the scale £2,118 to £2,412 with placement according to age, and is superannuable (F.S.S.U.).

Applications together with the names of two referees should be sent to The Secretary () Department of Chemistry, University of Stirling, Stirling by September 30, 1974.

(410)

LEEDS AREA HEALTH AUTHORITY (TEACHING)

Applications are invited from graduates in one of the Biological Sciences for the post of SCIENTIFIC OFFICER in the Regional Cytogenetic Unit established in the Pathology Department of this hospital. The Centre undertakes the cytogenetic investigations required for patients living within the area of the Yorkshire Regional Health Authority. Previous experience in cytogenetics is desirable but not essential.

Application forms obtainable by ringing Leeds 33144, extension 203 or 293 and should be returned to the Personnel Manager, St James's Hospital, Leeds LS9 7TF not later than 10 days after the appearance of this advertisement.

(409)

UNIVERSITY OF SOUTHAMPTON MEDICAL LABORATORY TECHNICIAN

to work for Department of Child Health in the University Medical Sciences Building. Duties involve operation and maintenance of cell culture apparatus and enzyme analysis and include development work and assistance with student research.

Qualification H.N.C. with related experience. Salary scale £1,848 to £2,163 or £2,007 to £2,382 according to qualifications and experience.

Applications in writing, giving details of age, qualifications and experience and the names and addresses of two referees, should be sent as soon as possible to the Deputy Secretary's Section, The University, Southampton SO9 5NH, quoting reference 262/T.

(430)

THE ROYAL DENTAL HOSPITAL
OF LONDON
SCHOOL OF DENTAL SURGERY
(University of London)
RESEARCH ASSISTANTS

Department of Physiology

Applications are invited for the appointment of Research Assistant in Physiology in relation to Dentistry. Applicants must be graduates in biological science preferably physiology and previous research experience is not essential. The post will be tenable for three years in the first instance and would permit registration for a higher degree as an internal student of the University of London. Salary range according to age and experience £1,400 to £1,713 (under review) plus L.A. and F.S.S.U. benefits. The successful applicant will be required to assist in work on the neurophysiological control of jaw function which involves laboratory experiments and the eventual application of data to clinical diagnostic procedures. As the School is in association with St. George's Hospital Medical School and Chelsea College opportunities for collaborative work exist with these institutions.

Department of Physical Sciences

A graduate Research Assistant is required by the Department of Physical Sciences to study ion-exchange and adsorption phenomena at the surface of hydroxyapatite, the mineral constituent of bones and teeth. Applicants are expected to have or to obtain a good degree in Physics or Chemistry. The appointment, which is for three years in the first instance, will be on a salary scale from £1,400 to £1,713 (under review) plus a London Allowance and F.S.S.U. benefits. Registration for a higher degree will be expected. Alternatively a part-time appointment would be considered.

Applications with curriculum vitae and the names of two referees should be submitted to the School Secretary, Royal Dental Hospital of London (School of Dental Surgery) 32, Leicester Square, London, W.C.2. and received not later than September 6, 1974. (418)

UNIVERSITY OF LEEDS
DEPARTMENT OF GENETICS

Applications are invited for a post-doctoral fellowship to work on amino acid replacements in mutant forms of *Neurospora* glutamate dehydrogenase. The post is available for one year (possibly renewable) starting as soon as possible, but no later than October 1, 1974; salary on the scale £1,929 to £2,388 (to be reviewed October 1, 1974).

Applications, together with the names of two referees, should be sent to Professor J. R. S. Fincham, Department of Genetics, University of Leeds, Leeds LS2 9JT, from whom particulars may be obtained. (426)

SIR GEORGE WILLIAMS
UNIVERSITY

Montreal, Quebec, Canada

DEPT. OF BIOLOGICAL SCIENCES
THREE FACULTY POSITIONS

Three faculty positions available, July 1, 1974: 1 Associate Professor (\$15,400 to \$17,000), 2 Assistant Professors (\$12,000 to \$15,000) depending upon experience and qualifications. Research orientated persons qualified to teach in one or more of the following areas will be considered: Embryology, Plant Ecology, Biostatistics, Introductory Biology. Ph.D. required. Send resume and names of 3 references to: Dr. H. Enesco, Chairman, Dept. of Biological Sciences, Sir George Williams University, Montreal, Que. H3G 1M8. (429)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF SURGERY
MEDICAL RESEARCH TECHNICIAN

required to assist with research into the biochemical aspects of liver disease. Experience with radio active isotopes an advantage but not essential. The laboratories are well equipped and will move into the new teaching hospital in the near future.

Candidates should be State Registered and salary will be on the Whitley Council Scale £1,557 to £2,451 per annum (plus threshold payments) according to qualifications and experience. Application forms may be obtained from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref RV/N/276145. (425)

Opportunities Overseas

Afghanistan

Cotton Adviser (Production and Extension)

To increase the production of cotton in the Helmand Valley by conducting extension work among farmers, advising on cotton production, controlling demonstration plots and helping to train local personnel. Involves liaison with extension staffs of the Cotton and Vegetable Oil Corporation and the Arghandab Valley Authority.

Appointment 2 years. Candidates should possess a degree or diploma in agriculture with extensive experience of the prescribed duties of the post.

Salary in scale £3,000 to £5,000 p.a. plus a variable tax-free overseas allowance in scale £365 to £1,295 p.a.

For full details together with an application form and booklet on Afghanistan, please apply giving age and brief details of qualifications and experience to:—

Medical Laboratory Technologists

3 years here could add a new dimension to your kind of work

As agents for Nchanga Consolidated Copper Mines, Zambia's largest mining group, we are looking for Medical Laboratory Technologists to work – on a 3 year renewable contract basis – at the Company's hospitals in Chingola and Kitwe, two important towns on the Copperbelt.

These hospitals serve not only the local and expatriate mining staff and their families, but also everyone for miles around. As a consequence, preventive medicine and also the public health and hygiene of whole communities have become major responsibilities. You will, in the course of your work, find yourself involved with the whole gamut of conditions and diseases peculiar to the Tropics – the kind of experience you might find hard to acquire elsewhere in one locality.

Take into account also the attractive life in a Copperbelt town, and the marvellously sunny Zambian weather and you can see how we can promise you an enjoyable time as well as valuable professional experience.

Qualifications: Applicants must possess at least FIMLT, offer practical experience in hospital laboratory routines, and be knowledgeable on modern bacteriological, bio-chemical and haematological techniques.

SALARY K 7,069 p.a. (£4,594 based on an exchange rate of K 1. = £0.65). Benefits include currency regulations advantages – up to 33½% of gross income can be sent home each month, with an additional end-of-contract allowance. Free passages to and from Zambia. A tax-free settling-in allowance of £390 if married and £195 if single. Free Life Assurance. A house or flat at a very low rent, and domestic help easily available. Generous paid annual leave. Company private primary schools available. Tax-free allowances for children's education and travel. Loan facilities to assist in car purchase. Medical aid scheme.

Write (enclosing details of professional qualifications and experience) for an application form and booklet to:

Anglo Charter International Services Limited
(Appointments Division), Department
7 Rolls Buildings, London EC4A 1HX.

Zambia's Copperbelt

an experience that counts for a lifetime

(488)

UNIVERSITY OF OTAGO

Dunedin, New Zealand

LECTURESHIPS IN ANATOMY

(Visiting or Established Posts)

Applications are invited from suitably qualified persons who can carry out research and teaching in neuroanatomy, or in embryology or in histology including cytology and who, in addition, either already have or are prepared to acquire experience in teaching gross anatomy. Demonstrated research capacity in some aspect of embryology or developmental biology would be an advantage.

While the vacancies are for established posts normally leading to tenure, the University is prepared to enter into discussions for short-term appointments for two years (although one year would be considered) with return air fares provided. The latter might interest recently retired anatomists.

Salary according to qualifications and experience within the relevant scale as under:

Science Graduate

Lecturer: NZ\$7,361 to \$9,339 per annum
Senior Lecturer: NZ\$9,503 to \$12,142 per annum with a bar at \$11,153 per annum.

Dental Graduate

Lecturer NZ\$8,303 to \$11,517 per annum
Senior Lecturer: NZ\$11,918 to \$13,121 per annum

Medical Graduate

Lecturer: NZ\$9,997 to \$14,287 per annum with a bar at \$11,811 per annum
Senior Lecturer: NZ\$14,699 to \$16,926 per annum

Further particulars should be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications, quoting ref. no. A.74/24, close in New Zealand and London on September 30, 1974. (431)

UNIVERSITY COLLEGE DUBLIN

Research Assistantship (full time)

or

Research Demonstratorship (part time)

Applications are invited for the above—which operate under a National Science Council Grant—in the Department of Geology. The appointments are for one year but may be renewed subsequently. A requirement is a good Honours Degree in Geology and preference will be given to candidates with practical experience in field or laboratory.

Salary:—

Research Assistant = £1,782 p.a.
Research Demonstrators = £891 p.a.

The latter post will permit demonstrating for which extra remuneration is made. Closing date for applications August 26, 1974.

Applications to

The Secretary,
Department of Geology,
University College,
Belfield,
Stillorgan Road,
Dublin, 4.

(423)

UNIVERSITY COLLEGE DUBLIN

RESEARCH POSTS IN INVERTEBRATE ECOLOGY

A post doctoral fellow or research assistant or postgraduate student is required for a 3-year project sponsored by the National Science Council on the organisation and dynamics of grassland invertebrate communities. Applicants should hold an initial honours degree in Agriculture or Zoology and preferably have research experience in quantitative ecology. Applicants graduating this Autumn will be considered.

Full details from:—

Dr. J. P. Curry,
Department of Agricultural Biology,
Faculty of Agriculture,
University College,
Glasnevin,
Dublin, 9.

(422)

QUEEN ELIZABETH HOSPITAL FOR CHILDREN

HACKNEY ROAD, LONDON E2 8PS

Applications are invited for the post of RESEARCH ASSISTANT in the Academic Department of Child Health at this hospital. The post is grant-supported and the successful applicant, who should have a good honours degree in biological sciences, will be expected to undertake a study of reaginic antibody in childhood asthma. Salary will be on the scale of £1,440 to £1,883. Applications with the names of two referees should be addressed to Pro. C. B. S. Wood, Academic Department of Child Health. (421)

AGRICULTURAL RESEARCH COUNCIL

UNIT OF DEVELOPMENTAL BOTANY

Application are invited from PLANT PHYSIOLOGISTS and BIOCHEMISTS for a two year temporary appointment as a SCIENTIFIC OFFICER/HIGHER SCIENTIFIC OFFICER at the Agricultural Research Council's Unit of Developmental Botany to investigate an aspect of the hormonal control of plant growth development. Candidates should hold post graduate qualifications and have some further experience in original research.

Appointment in grade of Scientific Officer £1,707 to £2,329 p.a. or Higher Scientific Officer £2,221 to £2,854 p.a. Starting salary in accordance with qualifications and experience. At least two years post graduate experience is required for appointment to H.S.O. Superannuation under F.S.S.U. with an allowance of 4½% of basic salary to off-set contributions.

The unit is attached to the Botany School of Cambridge University and is under the Direction of Professor P. W. Brian. Applications should be addressed to the Deputy Director, Dr. D. J. Osborne, Unit of Developmental Botany, 181A Huntingdon Road, Cambridge CB3 0DY. (435)

CHELSEA COLLEGE
University of London

TECHNICIAN GRADE 4

A TECHNICIAN (GRADE 4) is required for the Microbiology Section of the Department of Pharmacy, to undertake work involving the maintenance of the culture collection, preparation of cultures for undergraduate and post-graduate students and some field work for new experiments. Relevant experience and a List B qualification are essential. Salary in the range £2,023 to £2,338 per annum (including £228 London Allowance).

Application forms from the Manager of Technical Services, Department of Pharmacy, Chelsea College, Manresa Road, London SW3 6LX. (419)

UNIVERSITY COLLEGE, CARDIFF
DEPARTMENT OF BOTANY
RESEARCH ASSISTANT IN
PLANT BIOCHEMISTRY

Applications are invited from graduates in Biology, Biochemistry or Botany for the post of Research Assistant, to work on D.N.A. polymerase in higher plants, under the supervision of Dr. J. A. Bryant. The post is for a period of three years from October 1, 1974, with a starting salary of £1,422 (except in the case of an applicant who is allowed to register for a higher degree, for whom the salary will be adjusted to be equivalent to a post-graduate studentship). Further details are available from: The Registrar, University College P.O. Box 78, Cardiff CF1 1XL, to whom applications (including the names of two referees) should be sent by August 19, 1974. Please quote reference 0615. (436)

UNIVERSITY COLLEGE CARDIFF
Applications are invited for the following vacancy:
TECHNICIAN GRADE 3

in the Department of Physiology. Salary Range: £1,650 to £1,920 per annum. Duties to commence September 2, 1974. The post is for 15 months.

Applications, together with the names and addresses of two referees, should be forwarded to The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars may be obtained. Closing date August 9, 1974. Please quote reference 0616. (438)

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF PHYSICS

The Physics and Chemistry of Solids Research Group (Professor D. Tabor) of the Cavendish Laboratory hopes shortly to make appointments against posts concerned with the following projects starting in October:—

- The friction and wear properties of polymers and the influence of specific additives and fillers.
- Micromechanical properties in ultra-high vacuum of well characterised surfaces.
- The effect of minor constituents on the surface properties of solids.

Applications are invited from graduate and post-doctoral scientists with appropriate experience. Salaries on a scale between £2,118 and £2,931 p.a. depending upon age and experience.

Applications, incorporating a curriculum vitae and the names of two referees and noting the project(s) of interest, should be sent to The Secretary, Cavendish Laboratory, Madingley Road, Cambridge. CB3 0HE. (439)

UNIVERSITY OF ST ANDREWS
RESEARCH ASSISTANT IN
LASER PHYSICS

Immediate vacancy for a Research Assistant to work in the laser group on a CO₂ TEA laser contract. Previous experience in laser physics and high vacuum technology an advantage. Salary in the range £1,600 to £1,800 p.a., tenable for one year, possibly renewable.

Applications including a curriculum vitae and the names of two referees should be sent as soon as possible to Dr. A. L. S. Smith, Physics Department, University of St. Andrews, Fife from whom further details can be obtained. (441)

UNIVERSITY OF LONDON
CHAIR OF STRUCTURAL BIOLOGY AT ST.
GEORGE'S HOSPITAL MEDICAL SCHOOL

The Senate invite applications for this newly established Chair. Initial salary to be agreed but not less than £5,973 a year, plus £162 London Allowance. Applications (11 copies) should be received not later than September 10, 1974 by the Academic Registrar, (N) University of London, Senate House, WC1E 7HU, from whom further particulars may be obtained. (444)

LABORATORY ASSISTANTS OR TECHNICIANS
(CHEMISTS)

Two vacancies exist for young people in our Special Polymers laboratory and Sterile Solutions division to assist in production, research and development, covering a wide range of activities.

Candidates should ideally be qualified to HNC or equivalent in Chemistry or related scientific subject or alternatively be qualified by experience.

A realistic and progressive salary will be paid commensurate with age and qualifications. The usual Company fringe benefits apply.

Write in the first instance to:

Mr K. Gent,
Personnel Manager,
Contact Lenses (Mfg) Limited,
14/16 Child's Place,
Earls Court, London SW5 9RX
Tel: 01-370 4455.

(479)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF MATHEMATICS

RESEARCH ASSISTANTSHIP

Applications are invited for a Research Assistantship in the Department of Mathematics to take part in a theoretical investigation of rheological properties of pigment suspensions. Applicants should be well qualified in applied mathematics, or a related discipline, and have a good knowledge of contemporary continuum mechanics.

The post is for one year with salary up to £2,757 per annum, placing depending on age, qualifications and experience.

Further information (quoting R27/74) may be obtained from Dr F. M. Leslie, Department of Mathematics, University of Strathclyde, Livingstone Tower, 26 Richmond Street, Glasgow G1 1HX, with whom applications should be lodged by August 14, 1974.

(487)

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF APPLIED MICROBIOLOGY

Research Assistant

Applicants are invited for Research Assistantship to carry out an investigation on RNA dependent RNA polymerases in different strains of yeast. The work will involve the use of techniques in cell biology, enzymology and virology. Applicants should have a good Honours degree in Biochemistry or a related subject.

The appointment, starting on October 1, 1974, is supported by the Science Research Council until September 30, 1977, and the salary is £1,500 by £100 (2) to £1,700 per annum.

Applications (quoting R26/74) giving details of qualifications and experience, together with the names of two referees should be sent to Dr E. A. Berry, Department of Applied Microbiology, University of Strathclyde, Royal College Building, 204 George Street, Glasgow, G1 1XW.

(472)

TAX-FREE HOSPITAL OPPORTUNITY in SAUDI ARABIA

with **Whittaker**

The Whittaker Corp. represents one of the largest companies in the USA, which has diversified internationally into health care and environmental projects. We have been awarded a \$100 million contract to staff and manage three newly-built hospitals in Jiddah (60 beds), Tabuk (135 beds) and Khamis Mushayt (135 beds). The hospitals have been built to top US standards. Equipment is the latest and best from the USA and Europe, covering the full range of medical and surgical treatment.

There is an immediate opportunity on a two-year contract basis for:

Epidemiologist \$18,000

to study the incidence of communicable and chronic diseases and develop programmes and recommend courses of action for their control.

Candidates should be qualified in Public Health or Epidemiology with at least 2 years' experience in this field.

In addition to a tax-free salary, negotiable up to the maximum indicated, benefits include: free housing and messing; return passages for employees and families; generous baggage allowance and household storage provision; and 30 days' annual holiday.

ACTION—To meet our initial staffing requirements, this post must be filled quickly. Please URGENT write immediately with full biographical details, quoting reference U.123, to F. Sicher, Whittaker Corp., c/o MSL ADVERTISING SERVICES LTD. 17 Stratton Street, London W1X 6DB.

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL DEPARTMENT OF BIOCHEMISTRY M.R.C. Research Studentship

Applications are invited for an M.R.C. studentship which is available from October, 1974. Candidates should hold a good Honours degree in chemistry or a biological science. The successful candidate will pursue a course of research, leading to a Ph.D. degree, involving a study of changes which occur in the protoplast membrane of *Bacillus amyloliquefaciens* during the secretion of extracellular enzymes with particular regard to the metabolism of membrane phospholipids.

Applications and enquiries should be made to Dr. G. Coleman or Dr. D. White, Department of Biochemistry, University of Nottingham Medical School, University Walk, Nottingham NG7 2RD. Telephone 0602-56101. (446)

MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH BIOCHEMIST/MICROBIOLOGIST

A postdoctoral biochemist or microbiologist is required by the LABORATORY FOR LEPROSY AND MYCOBACTERIAL RESEARCH to investigate killing and degradation of mycobacteria by phagocytic cells. The work of the Laboratory includes several aspects of the relationship between pathogenic mycobacteria and their host cells. The appointment, which is for up to three years, is in the salary range £2,223 to £3,378 p.a. plus £162 p.a. London Allowance; superannuation provision under F.S.S.U.

Applications giving detail of qualifications, research experience and the names of two professional referees should be sent to The Director, National Institute for Medical Research, Mill Hill, London, NW7 1AA. (456)

UNIVERSITY OF SASKATCHEWAN

SASKATOON, SASKATCHEWAN,
Canada

Applications are invited for the following positions in the Department of Crop Science
PROFESSIONAL RESEARCH ASSOCIATE

A plant physiologist with experience in the field of identification and physiology of naturally-occurring plant growth regulators.
PROFESSIONAL RESEARCH ASSOCIATE

A plant physiologist with training and experience in the area of water relations and/or stress physiology.

The successful applicants will be part of a team of three scientists and three technicians who will undertake a comprehensive analysis of the role of plant hormones in drought stress in sorghum. The study, supported by the International Development Research Centre, Ottawa is designed to provide cereal scientists working in the semi-arid tropics with a more complete knowledge of the manner in which plant growth and productivity are influenced by drought stress. The project will take approximately five years.

The commencing salary for each position is \$12,924 plus a pension and annual increments currently equivalent to 5%. Minimum qualification is a Ph.D.

Further enquiries and applications, which close August 31, 1974, and letters from three referees should be sent to:
Prof. G. M. Simpson,
Crop Science Department,
University of Saskatchewan,
Saskatoon, Saskatchewan, Canada S7N 0W0
(440)

UNIVERSITY OF SOUTHAMPTON Senior Programmer

Applications are invited from graduates in Mathematics, or with a strong mathematical background, for the post of Senior Programmer in the Biology Department. The successful applicant will be expected to act as Computer Liaison Officer for the Department as well as developing and servicing computer programs. An interest in the application of computer-based techniques to biological problems is essential, and some knowledge of multivariate statistical methods would be an advantage.

Salary on scale: £2,580 to £3,636 per annum. Further particulars may be obtained from the Deputy Secretary's Section (Ext. 731), The University, Southampton SO9 5NH, to whom applications, with the names of three referees, should be sent by August 12, 1974. Please quote reference Na 902/0. (445)

THE QUEEN'S UNIVERSITY OF BELFAST

Research Officer/ Senior Research Officer

DEPARTMENT OF MICROBIOLOGY

Applications are invited for the post of Research Officer/Senior Research Officer in the Department of Microbiology. The duties of the post include assistance with investigations into persistent infection and with the preparation of teaching materials for classes in microbiology. Candidates for the senior post should have an ordinary science degree or equivalent, and the particular requirements for both grades of appointment are a knowledge of virology, tissue culture and experience with immunofluorescent and/or radio-active tracing of biological materials. In addition, candidates for the senior post should have experience in cellular immunology and the culture of cells from the immune system of animals and man.

The grade of appointment will depend on age and qualifications. The salary range for the Research Officer grade is £1,932 to £2,910 for the Senior Research Officer grade £2,952 to £3,990 both posts carry superannuation within the F.S.S.U.

Letters of application, giving the names of two referees, should reach the Personnel Officer, The Queen's University, Belfast, BT7 1NN, Northern Ireland by August 16, 1974. (437)

(489)

Royal Postgraduate Medical School TECHNICIAN, (Organic Chemist)

required in the peptide chemistry section of the Endocrine Unit, to assist with the synthesis of biologically active peptides. Qualifications: relevant 'A' levels, O.N.C. or H.N.C. in chemistry. Starting salary and grade according to qualifications and experience.

Applications to the Secretary, R.P.M.S., Hammer-smith Hospital, Du Cane Road, London W12 0HS, quoting ref. no. 2/322.N. (449)

UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG, SOUTH AFRICA DEPARTMENT OF PHYSICS

Applications are invited for the following posts:

- (A) Senior Lecturer
- (B) Lecturer
- (C) Junior Lecturer

- (D) Senior Lecturer with special responsibilities in the Faculty of Education

The persons appointed to posts (A), (B) and (C) above will take part in the general teaching and research work of the Department of Physics. Solid State Physics and Nuclear Physics are the two main research interests.

The principal duty attached to post (D) will be to organise in-service training for teachers of physical science in high schools.

Salary will be determined according to qualifications and experience within the following ranges:

Senior Lecturer: R7,245 to R9,315

Lecturer: R5,520 to R7,935

Junior Lecturer: R4,140 to R5,175

Improved salary scales are to be introduced shortly.

Benefits include an annual bonus, pension and medical aid, and a housing subsidy (if eligible).

Intending applicants should obtain the information sheet relating to these posts from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than September 20, 1974. (Please quote the post for which you are applying). U.K. applicants should obtain the information sheet from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1, to whom a copy of the application should be sent. (450)

EAST MALLING RESEARCH STATION

Head of Plant Protective Chemistry Section

A chemist with experience in pesticides required to lead the section concerned with pesticide usage on fruit and hops.

Appointment, according to age and experience, in the Principal Scientific Officer scale £4,227 by 7 increments to £5,550 together with the cost of living allowance and 4½% of gross salary to offset superannuation contributions. Superannuation under F.S.S.U.

Application form and further details from Assistant to the Secretary, East Malling Research Station, East Malling, Maidstone, Kent, ME19 6BJ. (451)

THE EDINBURGH SCHOOL OF AGRICULTURE AGRICULTURAL ENTOMOLOGIST

Applications are invited for a post in the Crop Health Department from candidates with post-graduate experience in Entomology/Nematology.

Salary scale (under review) Grade III £2,233 to £3,895 plus a cost-of-living safeguard and a non-pensionable supplement of 4½% to offset superannuation contributions.

Further particulars and application form from The Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (468)

NRDC

National Research Development Corporation Fellowship

Chemist/Biochemist

Applications are invited for a two-year NRDC Fellowship to work at the Microbiological Research Establishment, Porton Down (under the direction of Dr K. D. Macdonald), on the isolation, purification and characterisation of microbial metabolites with antibiotic activity.

Applicants should have two to four years' post-graduate experience, preferably with a knowledge of the chemistry of antibiotics both at a comparative and analytical level. Salary starting at £2,568 per annum rising to £2,675.

The appointment of a recent graduate with an interest in this field is not excluded and the salary would be in the range of £1,592 to £2,038.

'Threshold' payments will be made and annual leave will be 22 days.

Applications, with details of qualifications and naming two referees, to: The Assistant Director, Microbiological Research Establishment, Porton Down, Salisbury, Wiltshire SP4 0JG. (490)

NEW ZEALAND UNIVERSITY OF CANTERBURY CHRISTCHURCH

SENIOR LECTURERS or LECTURERS IN CIVIL ENGINEERING

Applications are invited for vacancies in the following fields: Highway Engineering; Public Health Engineering; Surveying and Town Planning.

The salary for Lecturers is on a scale from NZ\$7,361 to \$9,339 per annum and for Senior Lecturers NZ\$9,503 to \$11,153 (bar) \$11,484 to \$12,142 per annum.

Particulars, including information on travel and removal allowances, study leave, housing and superannuation may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on **October 31, 1974.** (461)

West Berkshire Health District MEDICAL PHYSICS TECHNICIAN

required for modern Isotope Laboratory at the Royal Berkshire Hospital, Reading. The post will be on Grade IV (£1,590 to £1,953) or Grade V (£1,308 to £1,677), and involves interesting work on the chemistry and physics of medical isotope techniques.

Candidates should normally have appropriate O.N.C. or 'A' levels. Day release for further training may be available.

Written applications to:

The Hospital Secretary,
Royal Berkshire Hospital,
London Road,
Reading,
Berks.

(455)

FRAME

which is concerned with disseminating information through its twice yearly Journal ATLA ABSTRACTS (Alternatives To Laboratory Animals) seeks a part-time scientific literature searcher and abstractor in the London area. For further details write to: The Secretary, FRAME (Fund for the Replacement of Animals in Medical Experiments) 312a Worple Road, London SW20 8QU. (459)

UNIVERSITY OF NEWCASTLE UPON TYNE

RESEARCH ASSOCIATE (BIOCHEMIST)

A Post-Doctoral Biochemist is required to participate in a three year project investigating the metabolism of foreign compounds by human skin, commencing in Autumn 1974 and being conducted jointly in the Departments of Dermatology and Pharmacology. Commencing salary up to £2,247 per annum with F.S.S.U.

Applications giving the names of two referees should be sent to Professor M. D. Rawlins, Department of Pharmacology, The Medical School, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, from whom further information may be obtained. (447)

University of Edinburgh RESEARCH ASSISTANTS

Required by the DEPARTMENT OF MOLECULAR BIOLOGY to work on genetic and biochemical aspects of prokaryotic molecular biology. The posts are grant supported for limited terms varying from two to seven years, and should appeal to holders of H.N.C., B.Sc., (Hons.) or a Ph.D. Salaries will be on scale £1,848 to £2,163 per annum. Threshold payment. Applications with names of two referees should be sent to THE PERSONNEL OFFICER, UNIVERSITY OF EDINBURGH, 63 SOUTH BRIDGE, EDINBURGH, EH1 1LS. TELEPHONE NUMBER 031 667 1011 Ext. 4446. Please quote Reference number A038. (454)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF PHYSICS RESEARCH ASSOCIATE

Applications are invited for a Research Associateship for up to three years under the terms of an S.R.C. grant in the Low Temperatures Group for the experimental study of electronic properties of quasi two-dimensional metallic compounds. Candidates should have a degree in physics and good experimental ability.

Salary:— £1,758 to £1,974 + F.S.S.U.

Applications (3 copies) naming 3 referees should be sent to the Assistant Registrar (S), P.O. Box 363, Birmingham B15 2TT, by August 26 1974. Please quote ref:— NP3. (476)

SURREY area health authority

West Surrey/North East Hampshire
Health District

DISTRICT PHARMACEUTICAL OFFICER

(PRINCIPAL PHARMACIST)

£3,522 to £4,185

To be responsible to the Area Pharmacist for the Hospital Pharmacy Service in the West Surrey/North East Hampshire Health District. The District Pharmaceutical Officer will be based at Frimley Park District General Hospital. The new department of health "best buy" hospital of 583 beds which is opening to out-patients on August 1, 1974.

Frimley Park Hospital is within short distance of London by train or road. Handy for reaching the South Coast Resorts and near the first class shopping facilities of Camberley.

Candidates with previous hospital experience who may now be working in other fields will be considered.

Application forms and job description from the District Administrator, West Surrey/North East Hampshire Health District, 3rd Floor, Abbey House, 282-292 Farnborough Road, Farnborough, Hants GU14 7NE.

Closing date August 9, 1974.

(492)

UNIVERSITY OF BRISTOL GRADUATE RESEARCH ASSISTANT in the DEPARTMENT OF BACTERIOLOGY

To start work in October on the role played by microorganisms in the production of pheromones. This three year investigation is part of a multidisciplinary environmental study of the Red Fox.

Initial salary up to £1,686 per annum.

Applications, preferably from microbiologists having some knowledge of Organic Chemistry (glc) should be sent to Dr G. C. Ware, Department of Bacteriology, Medical School, University Walk, Bristol BS8 1TD. (453)

MASSEY UNIVERSITY Palmerston North, New Zealand DEPARTMENT OF SOIL SCIENCE POST GRADUATE RESEARCH ASSISTANTSHIPS

Applications are invited from suitably qualified students for Post-graduate Research Assistantships in the Department of Soil Science. Applicants should have completed an Honours, or Master's Degree in Soil Science, Chemistry, or Microbiology and be interested in enrolling for a Ph.D. degree in Soil Science.

The areas of research relate to the transformation of nitrogen in soils, movement of nitrogen and phosphorus in soils as influenced by drainage and irrigation, and the biological availability of phosphorus in streams.

The appointments are for two years initially, commencing October 1, 1974 but extension to a third year is possible. No teaching duties are required.

Award: NZ\$2,400 per annum. (NZ\$1=\$A1=62p).

Further details of the positions and of the University may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on **August 23, 1974.** (463)

UNIVERSITY OF LEUVEN PHYSIOLOGICAL LABORATORY RESEARCH ASSISTANT

Applications are invited for three pre- or postdoctoral research assistantships. The persons appointed will be required to do research in electrophysiology and excitation-contraction-coupling of the heart (Prof. E. Carmeliet) or in renal and membrane physiology (Prof. R. Borghgraef) and to do some teaching to medical students. The appointments will be for two years. Salary between BF.390.000 and 460.000 per annum.

Further information may be obtained from Laboratorium voor Fysiologie, Dekenstraat, 6, B-3000 Leuven, Belgium, to which applications should be sent together with a curriculum vitae and the names of two referees. (482)

UNIVERSITY OF EDINBURGH DEPARTMENT OF CLINICAL SURGERY RESEARCH ASSOCIATE

Applications are invited for a post of Research Associate in the above department to take part in a project investigating the relationship between biochemical parameters and mammary cancer.

Applicants should have a degree in either biochemistry or biology. Experience in endocrine or biochemical techniques and work with experimental animals would be advantageous, but not essential.

Salary on scale rising to £2,757 with placement according to qualifications and experience.

Applications in writing, giving full details of qualifications and experience, and giving the names and addresses of two referees, should be sent to Professor A. P. M. Forrest, Department of Clinical Surgery, The Royal Infirmary, Edinburgh, 3. Please quote reference number 5038. (469)

THE INSTITUTE OF DEVELOPMENT STUDIES

at
University of Sussex

BRIGHTON BN1 9RE

Two Research Officers

Needed immediately to work with Michael Lipton on three year grain storage project in Rual India (Andra Pradesh) pilot project already completed.

(A) Crop Storage Specialist

(B) Agricultural Economist

Salary in range £1,761 to £3,378 (under review) with threshold agreements and overseas allowances.

Applications with C.V. and addresses of referees to Administrator Research within one week of publication date. (475)

UNIVERSITY OF OXFORD

DEPARTMENT OF ZOOLOGY

There is a vacancy for a research assistant to work on some aspects of insect neurophysiology with Dr. P. L. Miller for one year from October 1974. Applicants should have a good Honours Degree in Zoology. Salary in accordance with age and experience. Applications, with names of two referees, to Dr. P. L. Miller, Dept of Zoology, South Parks Road, Oxford. (481)

UNIVERSITY OF EDINBURGH DEPARTMENT OF SURGERY RESEARCH ASSISTANT

Applications are invited from biological science graduates for the above post to work on the association of alpha₂-macroglobulin with lymphocytes and its possible immunological significance.

The appointment is for three years and the commencing salary is up to £1,659 per annum, according to qualifications and experience.

Applications, together with the names of two referees should be submitted to Dr Keith James, Department of Surgery, University of Edinburgh Medical School, Teviot Place, Edinburgh, EH8 9AG. Please quote reference number 5036. (470)

GEOPHYSICIST

The Lamont-Doherty Geological Observatory of Columbia University announces a position with the seismology group as a Research Associate or Senior Research Associate. Candidates must have a strong background in seismic instrumentation and data analysis and will be expected to lead existing and initiate new programs of research involving observations of earth strain, tilt, and long-period seismic waves. Qualified candidates are invited to submit a resume of their qualifications, publications, names and addresses of three references by August 15, 1974. (460)

UNIVERSITY OF DUNDEE
DEPARTMENT OF PHARMACOLOGY
AND THERAPEUTICS
RESEARCH ASSISTANTSHIP

Applications are invited from University graduates or holders of equivalent qualifications for a Research Assistantship in the Department of Pharmacology and Therapeutics, located in the new Ninewells Hospital and Medical School complex, Dundee. The holder of this post, which is available immediately, will be required to provide a Gas-Liquid Chromatographic Service within the Department and to collaborate as required with other staff in research and teaching and will be afforded facilities to carry out his own research work on a part-time basis for a higher degree.

Applicants should ideally have had experience of gas-liquid chromatography but training in this will be available.

The salary attached to the post will be within the range £1,311 to £2,052 depending on qualifications and experience.

Applicants should apply, giving their qualifications, the names of two referees and quoting reference Est/39/74 J by August 9, 1974 to The Secretary, The University, Dundee DD1 4HN, from whom further particulars may be obtained. (477)

NATIONAL HEART HOSPITAL
WESTMORELAND ST, LONDON W1

**QUALIFIED TECHNICIAN
OR TRAINEE**

required to train in operation of Heart/lung machine and monitoring equipment in operating theatre and intensive care unit. Preference given to graduates studying for higher degrees or students attending evening classes. Day release facilities, however, may be given. Enquiries and applications to Assistant House Governor, telephone 01-486 0824 Ext 123. (491)

UNIVERSITY OF LONDON
KING'S COLLEGE

DEPARTMENT OF BIOPHYSICS

Applications are invited for the post of

RESEARCH ASSISTANT

to join a group working on the fractionation and crystallisation of transfer-RNA. The post is limited to two years, and would suit a recent graduate. Depending on qualifications and experience, the starting salary (including London Allowance) would be £1,746 or £1,920 till October 1, 1974, when new national scales will be effective.

Applicants should write (giving the names of two referees), to Dr N. Spencer, Department of Biophysics, (N) King's College, 26-29 Drury Lane, London WC2B 5RL. (483)

TISSUE CULTURE
Scientific Officer

required for work in Edinburgh on Animal Diseases. The appointee will be responsible for a wide range of experiments mainly involving nervous and lymphoid tissues as primary cultures and existing cell lines. Tissue culture experience is essential. Qualifications: a degree, H.N.C. or equivalent. Salary: £1,592 to £2,675, plus 5½% Superannuation allowance, according to qualifications and experience. Superannuation. Apply with names of two referees to: The Secretary, ARC Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ. (486)

**FELLOWSHIPS AND
STUDENTSHIPS**

INSTITUTE OF UROLOGY
(UNIVERSITY OF LONDON)

in association with St. Peter's Hospitals

Applications are invited for a Research Fellow (with medical and/or scientific qualifications), in the grade of Lecturer (Senior Registrar status), for an investigation into the ultrastructure of the kidney and urinary tract epithelium. The successful applicant will be attached to the Electronmicroscopy Unit in the Department of Pathology, St. Paul's Hospital. Appointment for one year in the first instance, subject to renewal for a further period of two years. Applications to the Pathologist (L), St. Paul's Hospital, Endell Street, London, W.C.2. (391)

COLAISTE NA hOLLSCOILE GAILLIMH

(University College Galway, Ireland)

Department of Physics

RESEARCH FELLOWSHIP—A graduate in Science or Engineering is invited to join a project on the utilisation of environmental energy especially wind energy.

The salary is £2,100 per annum and the post is tenable for at least two years.

Written applications with curriculum vitae and the names of two referees should be sent to—Dr T. C. O'Connor, Department of Physics, University College, Galway, from whom further particulars may be had. (399)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF BIOLOGY

Postgraduate Studentship

Applications are invited for a three year research studentship sponsored by May and Baker Limited to study aspects of the mode of action of foliage-applied herbicides, using radio tracer, chromatography and other techniques. The value of the award will be in line with normal postgraduate rates.

The successful candidate should possess a 1st or upper 2nd class honours degree in Biology, Biochemistry or Botany, and will be required to register for a higher degree of the University.

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to Professor W. W. Fletcher or Dr R. C. Kirkwood, Department of Biology, University of Strathclyde, Royal College, 204 George Street, Glasgow, G1 1XL. (473)

INSTITUTE OF UROLOGY
(UNIVERSITY OF LONDON)

in association with St. Peter's Hospitals

Applications are invited for a Research Fellow (with medical and/or scientific qualifications), in the grade of Lecturer (Senior Registrar status), for an investigation into the ultrastructure of the kidney and urinary tract epithelium. The successful applicant will be attached to the Electronmicroscopy Unit in the Department of Pathology, St. Paul's Hospital. Appointment for one year in the first instance, subject to renewal for a further period of two years. Applications to the Pathologist (N), St. Paul's Hospital, Endell Street, London, W.C.2. (390)

UNIVERSITY OF NOTTINGHAM
ALLIED BREWERIES RESEARCH
GRANT STUDENTSHIP 1974

Applications are invited for this studentship, tenable from September 1, to work under the supervision of Dr L. G. Briarty and Dr M. C. Pearson in the Department of Botany, School of Biological Sciences. The research project is concerned with the effects of atmospheric pollution on selected tree species in Sherwood Forest. The successful candidate will be expected to register for a higher degree. The value of the studentship is equivalent to the normal Research Council Studentships.

Applications and enquiries for further details should be addressed to the Department of Botany, University of Nottingham, University Park, Nottingham, NG7 2RD. Closing date for applications Wednesday, August 7, 1974. (400)

Department of Zoology,

UNIVERSITY OF READING

ICI Plant Protection Research Station
Jealotts Hill

Applications are invited from graduate chemists/biochemists for a Science Research Council C.A.S.E. studentship to investigate the mode of action of chemicals which interfere with chitin synthesis in insects. Candidates should write, giving the names of two referees, to Professor G. Williams, Department of Zoology, University of Reading, Whiteknights, Reading. (408)

UNIVERSITY OF SOUTHAMPTON
RESEARCH FELLOW
IN GAMMA RAY ASTRONOMY

Application is invited for the post of Research Fellow to work on the development of a balloon borne instrument to study direction of arrival and the temporal spectral characteristics of gamma ray bursts. Applicants should be familiar with particle counting techniques and associated electronic circuitry.

The post is initially for two years. Candidates should possess a Ph.D degree or equivalent qualification. Salary in range £1,929 to £2,388 (under review) plus F.S.S.U.

Applications including curriculum vitae and the names and addresses of two referees should be sent to the Deputy Secretary's Section, The University, Southampton SO9 5NH, quoting reference number: Na261/R. (412)

UNIVERSITY OF KENT AT CANTERBURY

Applications are invited for TWO POST-DOCTORAL RESEARCH FELLOWSHIPS in S.R.C. sponsored work on transport processes and point defect structure of fluorite lattices in collaboration with Dr. A. V. Chadwick (Chemical Laboratory). One appointment will be mainly involved with ionic conductivity measurements and the other with pulsed n.m.r. techniques. Previous experience in one of these fields, though not essential is desirable. Starting salary will be £2,118 p.a. Applications with curriculum vitae and the names of two referees should be sent to the Assistant Registrar, Chemical Laboratory The University, Canterbury, Kent CT2 7NH quoting ref. A64/74. Closing date August 23, 1974. (416)

MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH FELLOW

Applications are invited from graduates with experience in synthetic organic chemistry for a postdoctoral Fellowship for work on the synthesis of macrocyclic metal complexes as possible new dyes for wool, under the temporary supervision of Dr. David Collins, to whom further enquiries may be made. Appointment is initially until June 30, 1975 and is available for immediate tenure.

Salary range: \$A7,910 to \$A9,960 per annum.

Applications should be submitted in duplicate to the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria 3168, Australia, and should give age, qualifications and experience, and the names and addresses of two referees. Applicants should quote reference No. 41063.

Closing Date August 13, 1974.

The University reserves the right to make no appointment or to appoint by invitation. (432)

UNIVERSITY OF YORK DEPARTMENT OF BIOLOGY POSTDOCTORAL FELLOWSHIP

Applications are invited for a POSTDOCTORAL FELLOWSHIP to study structural and molecular aspects of the surfaces of cell plasma membranes. The project involves the application of environmentally sensitive fluorescent probe molecules. Experience in molecular aspects of membrane structure and immunology and/or the application of fluorescence techniques to biological problems is desirable. The post is supported by the Science Research Council.

Applications, with curriculum vitae and two referees, should be sent to Dr M. G. Rumsby, Department of Biology, University of York, Heslington, York, YO1 5DD, from whom further information is available. Please quote reference number 11/6025. (413)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF ZOOLOGY

One M.R.C. Studentship, tenable for up to three years from October, 1974, is available for a suitable candidate with a first or upper second class honours degree in a relevant biological science to study either the pharmacology of amino-acid receptors or the metabolic and sensory physiology of reptiles. Candidates would be expected to register for a Ph.D. degree. Written applications, giving details of qualifications and experience, and naming two referees, should be made immediately to Dr. P. N. R. Usherwood at the Department of Zoology, University of Nottingham, Nottingham NG7 2RD, marking the envelope MRZ. Alternatively, phone Nottingham 56101 extension 2212. (414)

UNIVERSITY OF ESSEX DEPARTMENT OF CHEMISTRY

Applications are invited for a RESEARCH FELLOW to undertake an investigation funded by the Science Research Council entitled 'Crossed molecular beam studies of elementary reactions'.

Qualifications in Chemistry, Physics or an Engineering subject would be appropriate. Further details are available from Professor J. N. Bradley, Department of Chemistry, University of Essex, Wivenhoe Park, Colchester, CO4 3SQ. Tel: 0261 44144 Ext. 2030. (457)

UNIVERSITY OF KEELE RESEARCH FELLOWSHIP IN BIOCHEMISTRY

Applications are invited for post of Research Fellow in Biochemistry Research Unit. The post is made possible by a grant from the Cancer Research Campaign. The appointee will join a team investigating the pharmacology of pinocytosis, and experience of cell culture would be an advantage. Salary on scale £2,118 x 129 x 165, with F.S.S.U. privileges.

Enquiries and applications to Professor J. B. Lloyd, Biochemistry Research Unit, Keele University, Staffordshire, ST5 5BG, to whom applications should be sent by August 31, 1974. (465)

TORRY RESEARCH STATION MINISTRY OF AGRICULTURE, FISHERIES AND FOOD NERC RESEARCH STUDENTSHIP

Applications are invited for a N.E.R.C. Research Studentship. Applicants should have, or expect to obtain, at least an upper second class honours degree or equivalent in Biology or Microbiology. The research will involve an ecological study of bacteria mainly from the aquatic environment with special reference to their biochemistry as an aid to their identification.

Applications with two referees should be sent in before August 23 to the Director, Torry Research Station, 135 Abbey Road, Aberdeen, AB9 8DG. (467)

SUBSCRIPTION – REDUCED RATE OFFER

The publishers appreciate that the inevitable high cost of an annual subscription to **Nature** restricts many regular readers to a circulation or library copy of the journal; these readers unfortunately do not enjoy the privilege of a personal copy to read at leisure and to keep for future reference.

To help such people we are making an offer (for a limited period) of a twelve months subscription for only £15 on condition that application is made on and within the terms described on the coupon attached. We regret that for the time being this offer can only be made to people with addresses in the U.K. and that it will be withdrawn on 31st October 1974.

If this experiment is successful, we hope to be able to repeat it and extend it over a wider area.

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is published monthly and sets out to cover all aspects of the fight for life of lakes, estuaries, seas and oceans. It includes news, comment, reviews and research reports not only on the threats of noxious substances to marine life but also on the management and productivity of the marine environment in general. It publishes accounts of new and proposed research programmes as well as the results of those in progress.

Recent research reports include:

Distribution of Caesium-137 in British Coastal Waters, D. F. Jefferies, A. Preston and A. K. Steele. **Export of Lead from Salt Marshes**, M. Banus, I. Valiela and J. M. Teal. **International Scope of Marine Pollution Damage**, D. P. Tihansky. **Effects of Red Mud on Marine Animals**, R. A. A. Blackman and K. N. Wilson. **Pollution Problem of the Golden Horn**, M. Karpuzcu.

Annual Subscription £6.00 (£7.50 USA and Canada). Prices applicable only to orders starting before 31 December 1974. Payment may be made in any currency at the current exchange rate. Cheques should be made payable to Macmillan Journals Ltd., Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

Studies in History and Philosophy of Science

Studies in History and Philosophy of Science is a quarterly journal which analyses the genesis, evolution and logic of scientific thought. It attempts to unite historical and philosophical approaches to science.

Recent papers include:

Maxwell's Methodology and his application of it to Electromagnetism, A. P. Chalmers. **The Astronomy of Eudoxus: Geometry or Physics?**, Larry Wright. **Conceptual Structures and Scientific Change**, Garry Gutting. **Whewell's Theory of Scientific Language**, Morton L. Schagrin. **Speculation in Physics: The theory and practice of Naturphilosophie**, Barry Gower. **Feyerabend and Galileo: the interaction of theories, and the reinterpretation of experience**, Peter K. Machamer. Edited by Gerd Buchdahl, Reader in History and Philosophy of Science, University of Cambridge and Professor L. L. Laudan, Chairman, History and Philosophy of Science, University of Pittsburgh. Published by Macmillan Journals Limited.

Annual Subscription £8.50 (£9.50 U.S.A. and Canada). Prices applicable only to orders starting before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

CHARLES C THOMAS • PUBLISHER

VENOM DISEASES by Sherman A. Minton, Jr., *Indiana Univ., Indianapolis, Indiana*. This volume will interest physicians who see envenomation as a clinical situation and students and investigators whose interest in venoms is in their chemistry, mode of action or evolutionary significance. '74, 256 pp., 63 il., 8 tables, \$11.75

ENVIRONMENT AND POLLUTIONS: Sources, Health Effects, Monitoring and Control by Francis K. V. Leh, *Univ. of California, Riverside*, and Richard K. C. Lak, *The Shell Company of the British Crown Colony of Hong Kong*. Various aspects of the global environmental problems are examined including the sources of air and water pollutants, the health and economic effects of air and water pollution, and the methods for pollution control. '74, 308 pp., 25 il., 7 tables, \$14.75

RESPONSES OF FISH TO ENVIRONMENTAL CHANGES. Edited by Walter Chavin, *Wayne State Univ., Detroit, Michigan*. (23 Contributors) New and definitive approaches to the problem of environment are created not only for aquatic environment and its biota, but to the solution of problems imposed by the ever-changing environment of man. '73, 472 pp., 166 il., 39 tables, \$19.75

HUMAN NUTRITION: Its Physiological, Medical and Social Aspects. A Series of Eighty-Two Essays (2nd Ptg.) by Jean Mayer, *Harvard Univ., Boston, Massachusetts*. One of the best-known nutritionists of this era discusses the scientific, clinical and administrative aspects of nutrition and their relation to health, poverty, war and technology. '74, 740 pp., 5 il., \$12.95

BLOOD COMPATIBLE SYNTHETIC POLYMERS: An Introduction by Stephen D. Bruck, *National Institutes of Health, Bethesda, Maryland*. This introductory book contributes to the development of a satisfactory dialogue among physical and biological scientists, physicians and engineers working in the area of blood compatible materials. It represents an effort to bring together the diversified theories that are involved in the understanding of the interactions between synthetic polymers and blood. '73, 142 pp., 69 il., 14 tables, \$9.75

THE BOTANY AND CHEMISTRY OF HALLUCINOGENS by Richard Evans Schultes, *Botanical Museum of Harvard Univ., Cambridge, Massachusetts*, and Albert Hofmann, *Sandoz Ltd., Basel, Switzerland*. Foreword by Heinrich Kluver. Directed primarily toward the botany and chemistry of hallucinogens, the book also considers ethnobotanical, historical, pharmacological and psychological aspects. '73, 292 pp., 85 il., 5 tables, \$14.75

NARCOTICS AND NARCOTIC ADDICTION (4th Ed.) by David W. Maurer, *Univ. of Louisville, Louisville, Kentucky*, and Victor H. Vogel, *California Narcotic Addict Evaluation Authority, Ben Lomona*. The most recent findings on narcotics, narcotic addiction and the addict are presented objectively and in full detail. '73, 496 pp., 32 il., \$15.75

Volume 2

53 plates. XIV, 230 pages. 1974

Loose-leaf, boxed DM 42,70* ISBN 3-540-06529-6

Modern techniques for the preparation of mitotic cells of nonmammalian vertebrates permit close comparison of taxa in the classes: fishes, amphibia, reptiles, and birds. This Atlas presents karyotypes of 52 species, some previously published but widely scattered, and some published here for the first time.

It is planned to bring out one volume per year containing some 10 to 15 karyotypes from each class.

Contents: Pisces: Perciformes, Atheriniformes. Siluriformes. Cypriniformes. — Amphibia: Anura. Urodela. — Reptilia: Squamata. — Aves: Rheiformes. Charadriiformes. Passeriformes. Strigiformes. Apodiformes. Galliformes. Anseriformes.

Volume 1

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Development of polycystic ovaries in rats actively immunised against T-3-BSA— S. G. Hillier, G. V. Groom, A. R. Boyns and E. H. D. Cameron	433

Medical policymaking in Britain

If there is any subject that is guaranteed to generate boredom amongst scientists it is science policy. The average practitioner believes, with some justification, that whereas it would be most undesirable for a country to eschew a defence policy and leave all decisions, from procurement to strategy, to the soldier in the field, the scientist should be immune from policy constraints.

This system, in which the majority of scientists have received the majority of what they asked for and have in general been answerable only to their own consciences and to a relatively genial sponsor, is beginning to crumble as the growth rates for expenditure on research drop dramatically and as the demand for accountability rises sharply. Within the next year or two many scientists will indeed discover that there is such a subject as science policy, and arid and irrelevant as it may have seemed in the past, it is science policy that will decide whether their project will continue to be funded. The recent publication of the Medical Research Council's Annual Report (HMSO, 97p) is an appropriate time to look at the policymaking machinery in the biomedical field, and the report is generous in its attention to policy. The council is still able to say that "the ideas and interests of the individual scientists at the bench are the driving force behind science", although it adds in the next sentence "there may also need to be active discouragement of over-populated but low priority areas"—a fairly even-handed way of mixing good and bad news.

And yet there is something strangely and almost intangibly missing from the report. It is most easily seen in the section describing progress in research on selected topics. One gets the unmistakable impression that the Medical Research Council is the last bastion the world has against disease and death. The report is of course addressed primarily to the Secretary of State for Education and Science (who is told in the second paragraph of the transmittal that for £1.00 he can buy the council's Handbook from headquarters), and as such necessarily must remark on the successes that government money has bought. Nevertheless there remains just the vaguest feeling throughout the policy section that this is policy for medical research determined by the Medical Research Council without mention of the fact that a quite substantial amount of research is done by other research councils, by charities and trust funds, and by the pharmaceutical industry. Of course, excellent liaison may exist, although it doesn't shine through. And it is obviously desirable to allow a multiplicity of funding sources to exist so that power does not reside solely in one council, however appointed. But if it is indeed the function of the MRC to promote the balanced development of medical and related biological research and if all research programmes are going to fall on harder times in the next year or two it would be good to know that policymaking reflects the 'mixed economy' nature of Britain's support of medical science.

Dear Mr Turner . . .

By August 1 you had hoped to have appointed several research fellows to pursue fundamental biological research. Instead, as everyone now knows, you came into conflict during the selection procedure with potential recipients of the awards who objected to your refusal to consider those who had religious beliefs of one kind or another. No doubt you feel sore at all this and believe that there are fundamental inconsistencies between religion and science which cannot be glossed over by research scientists.

You are by no means alone in your doubts that the pursuits of science and religion are incompatible occupations; indeed I suspect that amongst businessmen it may be a majority view. Of course, there are many scientists whom you would probably happily exclude from your strictures—those working in agriculture, medicine, materials and so on are presumably exempt, but you would probably wish to retain those subjects which move close to the problems of man and the universe, such as astronomy, geology and those branches of biology that are concerned with the nature of life. How, you might say, could someone dare to contemplate an idea in these fields which struck at his own personal convictions.

As you know, there have been scientists of great

distinction who have held very strongly to religion and, one suspects, many more who have believed in some underlying purpose to the universe without feeling that they had to devote an hour to it every Sunday. Perhaps some were inhibited from peeping too far behind the scenes, although I know of none, but many more were positively driven on by their beliefs to understand more about a universe at which they marvelled.

Furthermore successful scientists learn flexibility early in their training—they cannot afford to become too committed to conventional wisdom because they are there to discover, not to reinforce. Thus they are unlikely to hold fast to any religious beliefs with which they know their research might bring them into conflict. They are also pragmatic and like fame as much as anyone else, so they are not going to stand by for the sake of religious beliefs whilst someone else finds a cure for cancer or a recipe for longevity.

Most scientists would have found it extraordinarily difficult from their personal experiences in the fields I have mentioned to categorise scientists as religious or otherwise from their mode of working and their approach to fundamental questions. You would probably have found the same.

Call for biohazard legislation

In this article Brian J. Ford argues that the law does not concern itself sufficiently with the various hazards that can arise when microorganisms are mishandled and suggests areas in which legislation should be introduced.

LEGAL restraints and regulations are the bane of research workers in many spheres. All of us must have felt some kind of annoyance at the filling in of forms or the signing of registers that have the aura of state bureaucracy, but the justification lies in the resulting safety of research. If that is the case, it is odd that legislation covering the handling and use of microorganisms and viruses that are pathogenic to mankind is virtually nonexistent.

At the moment moves are afoot in Britain to make hepatitis a recognised industrial disease amongst hospital and laboratory staff, and there is in the United States a call for a moratorium on microbial genetic manipulation. Such piecemeal short term measures could be superseded by the greater controls of a generally accepted legal framework of safety.

In other fields of scientific endeavour there are laws that regularise the use of potentially dangerous materials. Strict controls govern the use and distribution of radioactive substances, even those of the lowest potency used in student demonstrations. Toxic chemicals are subject to a range of long standing controls including the pharmacy and poisons legislation, the poisons rules and the legal restraints on dangerous drugs. In the First Schedule of poisons appear compounds great and small, from TEPP to 2-methoxycarbonyl-1-methylvinyl-diethyl phosphate; yet there is no reference to the bacterial toxins which are considerably more dangerous and also, in many respects, easier to produce.

In the regulations governing the security of the experimental animal appear rats, mice, rabbits; even dogs and cats. There is no mention, however, of pathogens. In the world of agriculture there are restrictions on the handling of some plant pathogens of economic significance and on the culture of viruses such as foot-and-mouth, though limitations on human pathogens are absent.

In philosophical terms the greatest hazard posed by the lack of controls

over pathogens is their infectivity: poisons do not replicate. A technician who takes home an isotope may damage himself as a result, whereas a mis-handled culture of virulent microorganisms could expose entire communities to widespread hazard. Yet isotopes are kept under lock and key. It is a culture of pathogenic microorganisms that needs no such safeguard in the eyes of the law.

Since I first published an outline of proposals for biohazard legislation (*New Law Journal*, 121 (5511), 823-824; 1971) there have been several examples of the misuse or abuse of cultures pathogenic to mankind. That paper referred to the virus of smallpox (variola) and the occasional accidents that occur when unsupervised or inexperienced staff come into contact with pathogens. Last year's outbreak in the London area is a tragic illustration of the hazard.

Children have recently been found playing with discarded culture vessels in the Midlands; and others were found to have obtained contaminated syringes casually discarded by a pharmaceutical concern in Kent. Occasionally cultures are wilfully misused. In the United States it has been reported that an underground group planned to immunise themselves against the effects of bacteria that were then to be introduced into the public water supply, and in Australia a culture of a meningitis virus was stolen (in its incubator) from a research laboratory.

Examples are known where disease has resulted from the use of unplugged mouth pipettes. A recent example in Britain involved a supposedly non-pathogenic bacterium ingested when

the tip of a pipette under suction was momentarily withdrawn from a thin agar culture. Elsewhere an assistant handling positive sera from syphilitics made a similar error, but did not develop the disease. I have seen a technician attempt to open a phial of polyvalent poliovirus, believing the glass to be scored. It was not, and the neck fractured and lacerated his finger.

It had not been ascertained whether he was immune to polio before commencing his work with the viruses. A similar case concerned a girl technician who saw her doctor with a sore throat, contracted shortly after she began to work with diphtheria. No check had been made on her immunological status and following representations made by the doctor to the college department the entire research team was immunised as a precaution. At a university zoology department, to cite another example, staff set up a tank for the rearing of water snails infected with bilharzia. A small child related to one of the staff dabbled its hand in the water on the morning before the parasites were introduced.

In each of these episodes some safety measures were subsequently introduced to prevent a recurrence. But retrospective, custom-built regulations are no way to prevent accidents entirely. We now have a situation where safety codes in a laboratory tend to be based on the past history of accidents in the establishment. Biohazard law would enable general safety measures to be introduced and enforced for the protection of all.

The literature of the past five years has included several examples where widespread hazards might have been involved. A form of infectious choriomeningitis reportedly caused five cases with three fatalities during experiments in the United States, and an unidentified virus from vervet monkeys has been stated to have caused over 30 cases with seven deaths despite the most rigorous attempts to contain the virus. Venezuelan equine encephalitis is now said to be epizootic in Utah, having originated in biological warfare experiments.

Many hazards arise from the failure to maintain adequate supervision in laboratories. Junior or untrained staff may be given access to culture materials they do not understand. In some cases infected materials are disposed of by being poured down the same sink as

Smallpox virus particles

*The revealing lens, 19th century version.
A William Heath etching of the 1820's
depicts the contemporary view of
microbiological hazards*

that used for the preparation of tea and coffee.

There are interesting precedents in British law for the kind of proposals I envisage. The Factories Act 1961, Section 64, provides for the minister to extend the provisions banning eating in places where fumes or dangerous industrial dusts are produced; there is no mention of the far greater hazards that have biological origins (and, as the important case of *Weston v LCC* (1941) showed, a technical institute is not a factory).

The conduct of workers in laboratories has an interesting precedent in the Agriculture (Poisonous Substances) Act 1952. Section 1 Subsection (c) calls for the "abstention from eating, drinking and smoking in circumstances involving the risk of poisoning" and Section 2 Subsection 1 (b) makes it a culpable offence to do anything to "wilfully . . . cause risk of poisoning". Similar precautions with respect to microorganisms and viruses would not be hard to define.

The Radioactive Substances Acts, 1948 and 1960, define in detail the conditions under which radioactive substances should be handled, distributed, stored and controlled. The clear restriction of the availability of radioactive materials to "duly qualified medical practitioners or registered dental practitioners" is similar to what might be proposed for virulent pathogens. The Factories Act 1961 Section 18 Subsection (2) refers to the avoidance of dangers from "scalding, corrosive or poisonous" materials, to which list the infection risk could be appended. Section 82 of the same Act contains an anomalous, isolated reference to bacterial hazards when it refers to illnesses caused by lead, phosphorous, arsenic, mercury "and anthrax" as notifiable conditions, without reference to other infections of an occupational origin. The widespread use of microorganisms in industry, which an extension of biological engineering will inevitably entail, makes safeguards timely.

Conditions of storage have been covered in respect of phials containing vaccines, antibiotics and related biological products under Part III Section 5 (i) of the Therapeutic Substances Act 1956, which states that such containers must be sealed to "preclude the access of microorganisms" and later specifies the labelling of the outsides of the

containers. A universal biohazard mark for glassware and other apparatus used to contain pathogens should be found. Perhaps a yellow spot or disk could be fused into glassware during manufacture as a permanent warning against the casual use of beakers or flasks for the preparation of refreshments. The recently introduced biohazard symbol displayed in some laboratories, or something like it modelled on the radiation sign, should be obligatory in all establishments handling pathogens.

Certain diseases are already notifiable, of course; though it is interesting that an organism in one's gall bladder may lead to restrictions by the health authorities which they would be powerless to impose if the organisms were carried, in a bottle, in one's trouser pocket instead. The only substantive reference to microorganisms occurs in the Therapeutic Substances Act Part II Section 4 (b) of 1956. It requires that separate laboratories be provided by licensees producing medical products if they "engage in the culture or manipulation of pathogenic spore-bearing microorganisms". It is already recognised by this Act that pathogenic contaminants must be kept out of containers of vaccines and the like, though the converse possibility—that organisms allowed to escape from within containers may pose even greater problems—is not referred to.

By far the greatest indictment of the current situation is the framework of controls within the Public Health Act 1936 and 1965; and the Health Services and Public Health Act 1968 (as amended by Schedule 14 and para 4 of Schedule 29 to the Local Government Act 1972).

These regulations contain a host of strictures on those unfortunate enough to contract smallpox, with limitations

on the movement of people concerned and the use of library books and dustbins during an outbreak. The possibility that restrictions should be placed on the *in vitro* virus remains ignored.

Legislation should cover several specific areas:

- It should define groups of organisms, such as those of high pathogenicity (variola, tubercle, typhoid) which are not normally present in the environment but which pose problems to communities. These I have grouped as 'Schedule A' pathogens. The remainder, including streptococci and staphylococci, are widespread and should be subject to more basic safety regulations in the laboratory: these would constitute 'Schedule B' and would alone be available for school and teaching use.

- The status of licensed holders of Schedule A organisms and viruses would be defined in terms of academic training responsibility and seniority. Less severe restrictions would be placed on laboratories classified for the culture of Schedule B pathogens.

- Standards of safety in laboratories would be laid down and codes of conduct made mandatory. The registration of holders of specified pathogens would doubtless aid the coordination of the research effort, and clear sets of agreed criteria would apply to genetic manipulation of bacteria and viruses, and to the disposal of potentially hazardous materials.

It is indeed unfortunate that bacteria and viruses are still so widely seen as harmful. To many of them we owe our very existence. Yet they confer on the research worker considerable responsibility when he comes to work with pathogens *en masse*. A legal code is now overdue for academic, practical and humanitarian reasons. □

international news

Two groups which have long been advocates of arms control and of detente between the United States and the Soviet Union last week condemned as "a counterproductive sham" the so-called test ban agreement which the besieged Mr Nixon brought back from Moscow. Suggesting that the agreement will do more harm than good in preventing the spread of nuclear weapons, the two groups—the Federation of American Scientists (FAS) and the Arms Control Association—called on Nixon to renegotiate a more meaningful arms control measure instead of sending the Moscow test ban treaty to the Senate for ratification.

A so-called "threshold" ban, the agreement would prohibit the United States and the Soviet Union from testing nuclear weapons with a yield greater than 150 kton. It is not due to be brought into effect until March 31, 1976. But it does not cover so-called "peaceful" nuclear explosions and it is simply a bilateral agreement between the Soviet Union and the United States, with no provision for other countries to become parties to it.

The FAS and the Arms Control Association believe that the treaty will do nothing to limit the number of tests conducted by both countries and that it will be seen as "a complete and cynical fraud" by countries which do not now possess nuclear weapons and which are looking to the nuclear powers to show some restraint in weapons development. In short, they argue that the Moscow agreement is worse than nothing.

They base their condemnation of the measure on four chief grounds.

- The 150 kton threshold—which is ten times greater than the bomb which devastated Hiroshima—is so ludicrously high that it will allow the United States and the Soviet Union to continue testing virtually unchecked. Furthermore, since it will not be introduced for nearly two years, both countries will probably carry out what the Arms Control Association calls an "orgy of intensive nuclear testing" in order to get some large tests in before the deadline.

- There are at least two, and possibly three, weapons systems which will have to be tested before the limitation comes into effect. First, a new warhead which is being developed for the Minuteman III, with a yield of about 400 kton, will have to be extensively

Test ban treaty condemned

by Colin Norman, Washington

tested. Second, a new bomb or perhaps an air-launched missile will have to be developed for the B-1 bomber. And finally it has been suggested that the missile for the new Trident submarine may have a yield of 200 kton; that too will have to be developed before the treaty takes effect.

- As for the Soviet Union, the chief programme which will be affected will be the development of MIRVs for the big SS-18 missile. Although according to some accounts testing for that device may already be completed.

- Aside from these weapons, there is little need for either country to conduct large tests—indeed, since the partial test ban was signed in 1963 the vast majority of tests have been below 150 kton—and so the FAS believes that the treaty will have little effect on weapons development. Thus seen from the viewpoint of non-nuclear countries, the agreement is a sham which does nothing to fulfil the commitment enshrined in both the partial test ban treaty and in the nuclear nonproliferation treaty to bring about a complete halt to weapons testing.

Equally counterproductive as far as stopping the spread of nuclear weapons is concerned is the fact that the agreement does not cover explosions for peaceful purposes. Since India justified its recent nuclear test as a perfectly peaceful enterprise—an interpretation which has been greeted with great scepticism outside India—FAS and the Arms Control Association believe that the Moscow agreement will increase the chances of other countries following India's example. As Adrian Fisher, former deputy director of the Arms Control and Disarmament Agency, put it last week, the agreement "legitimises the Indian position" at the time when everybody is attacking it.

The FAS also points out that the test agreement may pose severe political problems because of difficulties in ensuring that it is not violated. For one thing the treaty provides for calibration shots to be carried out at each country's test site, but FAS notes that "we cannot know the yield of the Russian weapon from examination of seismological data

for reconnaissance. It could be 300 kton instead of the stated 150 kton". And for another, the same explosive force can give different seismological signals of differing strength, depending on where and how it is fired.

Finally, and perhaps most important, there is considerable concern that if this essentially meaningless agreement is ratified it will, in the words of the FAS, "sell out the efforts to reach a comprehensive ban" on nuclear testing by "retreating on policy grounds and taking the matter off the national agenda".

Thus FAS and the Arms Control Association are suggesting that the treaty should be renegotiated, with the objective of securing a complete embargo on nuclear tests. In any case, it is worth pointing out that some 37 senators, led by Edward Kennedy, sent a letter to Secretary of State Henry Kissinger during negotiations on the Moscow agreement asking that a comprehensive rather than a threshold agreement be negotiated. If they all stand firm in their belief that the Moscow agreement is meaningless in terms of control, they have enough votes to block its ratification if it is referred to the Senate.

If the matter is renegotiated, what grounds are there for believing that the Soviet Union would be prepared to negotiate a complete test ban? Two statements of Chairman Brezhnev are being widely quoted as giving a hopeful indication. First, on June 14 he said that the Soviet Union "was prepared to reach agreement now with the United States on the limitation of underground nuclear tests, proceeding to their full termination according to a coordinated timetable". And second he said in a speech on July 21 that "we would like to achieve something more and are prepared to go further; the Soviet Union is ready in particular to conclude an agreement on complete cessation of all underground tests of nuclear weapons".

It is widely assumed, however, that it was the Soviet negotiators who were most insistent in exempting peaceful nuclear explosions from the Moscow agreement, and that it could present a huge problem in any future negotiations. As the FAS succinctly put it, "the question arises of either talking the Soviet government out of its interest in peaceful uses or deriving an acceptable method of verification".

FOLLOWING hard on the heels of long awaited decisions about British nuclear power and oil comes the not unexpected news that the Maplin project for a 'third' London airport is to be abandoned. The decision has been made in the light of a reappraisal of the project made since the British election earlier this year, and comes just after the publication of the British Airports Authority (BAA) *Annual Report 1973/74* (HMSO, £2).

In that report, the Chairman of the BAA, Nigel Foulkes, commented: "The financial year brought a series of events which reduced the BAA's profits, slowed down the growth rate of the air transport industry sharply, and put all long-term plans for the future development of our airports back into the melting pot". What has now emerged from that melting pot is evidence that no further main runways will be required to handle expected traffic at the four airports in the London area

Maplin project abandoned

(Heathrow, Gatwick, Stansted and Luton) before 1990. With the noise nuisance now likely to be lower than forecast by the Roskill Commission (thanks to the advent of quiet wide-bodied jets) there is no need for a new airport at least until that time.

Capacity at both the principal London airports would have to be increased whether or not the Maplin project went ahead, the Secretary of State for Trade, Mr Peter Shore, told the House of Commons on July 17. The growth envisaged is from a capacity to handle 20 million passengers a year to 38 million in the case of Heathrow, and from the present 6 million passengers a year to 16 million for Gatwick.

If air traffic expands so that even this capacity is insufficient to meet the demand, various possibilities will be

open to the planners of the mid-1980s. Stansted, which has been referred to as the "expansion chamber" of the existing British airport system, must once again seem high on the list for future development, and although Mr Shore commented in the House that major diversion of traffic from the south-east to airports beyond Bournemouth, Birmingham and the East Midlands does not seem attractive at present, in the long term there is still a possibility of developing airports as far away as Prestwick and Edinburgh. With the higher speed rail links which would be possible by the 1990s, such a diversion might then have more appeal.

Whatever happens in the long term, in the present atmosphere of uncertainty about air traffic and with general economic stringency, many will, no doubt, echo the words of Mr Eric Moonman, Member of Parliament for Basildon: "To save £650 million is a good afternoon's work".

LORD ROTHSCHILD said in 1971, a year after the appointment of a Central Policy Review Staff (CPRS) or 'think tank', that its and his success could be measured in terms of its survival. It had then survived somewhat longer than the equally novel Department of Economic Affairs—a parallel he drew—and this was despite the unnecessarily disruptive rumpus caused by the blunt instrument of the White Paper on the reorganisation of government research funding. The think-tank's continuation has now been officially endorsed by the present Labour administration and so tacitly subsumed as a permanent piece of government machinery, but Lord Rothschild is opting out. His successor as head of the CPRS is Sir Kenneth Berrill, a Treasury economist and former Chairman of the University Grants Committee.

The virtue of the original think-tank (whatever its shortcomings) was that it was Lord Rothschild 'writ large'. The fifteen or so bright young men that formed its analytical staff were all of his personal choosing. He was not, nor ever could be, a conditioned civil servant. His independent means removed him from the servitude of security in presenting his opinions—though he has questioned the relevance of this. His background lay in demanding fields of observational science and experiment, his foreground in multinational industrial research planning in his 10 years as research director of Shell Chemicals. All the indications are that however strange the advice proffered by Lord Rothschild's think-tank it was genuinely independent. The change can only mean a reduction in the role of science in government, especially as the post of Chief Scientific Adviser has also lost status recently. Does the government really want informed, independent pacing of its

Last of the great independents?

performance 'within the system'?

Two years ago Lord Rothschild assessed the importance of the CPRS as follows: "Regional policy is the most intractable problem we have been faced with, but the most difficult and important is this analysis of the government's strategy". Perhaps today he would reassess the relative intractability of the subjects under study.

In general the subjects which the Cabinet has referred to the CPRS are confidential—as are the recommendations made. But it is known that apart from government research funding, inflation and energy it has studied Concorde, the British computer industry, the Post Office giro, whether there is an optimum population level for the nation, multinational companies and the bane of all governments, regional policy.

The think-tank has, under various circumstances, published three of its 'thinks'. There was (and is) the redistribution of

government research funds which threw Lord Rothschild himself into public prominence and is still somewhat controversial. He has continued to maintain that before the White Paper's adoption "the organisation of government science was wrong" but has subsequently admitted "the only real regret I have is that I did not explain the customer/contractor principle. I didn't explain it because I thought it self evident. But it evidently was not so." If he had, this would have made the report three times as long but perhaps "some of the scientists would have been less hostile".

The study on population has also been published and most recently the think-tank's long gestated views on energy were drilled out of the government machine by the Secretary of State for Energy, Mr Eric Varley. Nonetheless the think-tank published first and its emphatic reliance on saving energy rather than flirting with alternative energy sources was firmly lodged in the Department of Energy's paper which appeared a fortnight later. Particularly appealing features of the CPRS's *Energy Conservation* were the emphasis on an industrialists' 'annual energy audit' the possibility of saving substantially on electric light bulbs and the criticisms of large, fast uneconomic private cars. It would be a fitting memorial to Lord Rothschild's quirky reign in Whitehall if he could get public acceptance of a slow, small economical battery-driven urban runabout.

In the meantime, it seems that the CPRS is being downgraded with Rothschild's departure. Mr Wilson has already appointed a parallel unit of about eight advisers, currently untitled, but effectively an economics think-tank within No. 10 Downing Street itself headed by Dr Bernard Donoghue.

Those babies still pose problems

by Miranda Robertson

It has not been entirely clear from press reports over the past two weeks that no child in the immediately foreseeable future is likely to have been in any sense a test tube baby. The most that is contemplated is the occasional emergence—in the traditional manner, from a woman—of a baby which spent its first few days as a fertilised ovum in a Petri dish (test tubes are not used for this kind of thing). That much is in principle quite possible and even desirable, although there are good reasons for supposing, in spite of claims at the recent British Medical Association meeting in Hull, that it may not yet have happened.

Scepticism about Professor Bevis's announcement could only be abolished by the publication of a technique which proved more successful than those already reported. The existence of three children, even if they were born to couples who had taken part in artificial in ovulation trials, cannot vindicate the claim: where the wife is the egg donor and the husband the sperm donor, there is no way of telling whether the baby developed from the reimplanted egg, or whether it was naturally conceived in the course of the experiment, as can sometimes happen with presumed infertile couples.

The transfer of eggs fertilised outside the body into the uterus to complete development is already routine in laboratory animals used in genetic and developmental research. It is somewhat trickier to get eggs from humans than it is from mice or rabbits, but even so the techniques for obtaining viable fertilised human ova, developed over the past few years in Britain by Mr Patrick Steptoe of the Oldham and District General Hospital, and Dr Robert G. Edwards, of the University of Cambridge, are now extremely reliable. The problems which have prevented the animal success from being extended to humans lie not within the embryo but with the reproductive physiology of the mother in whose uterus the embryo must be able to implant.

It is not particularly surprising that the fourteen egg transfers so far reported by Mr Steptoe have failed. Even in mice, the failure rate for implantation of transferred eggs is something like 50%. There is every reason to suppose that some proportion of all fertilised eggs in normal women fail to implant and are flushed out, unnoticed, with the next menstrual flow. Patients whose infertility is an indication for artificial in ovulation are not normal women. The blocked oviducts which

makes the procedure necessary are likely to be the consequence of disease which may have had other effects on the reproductive apparatus. The very procedure of injecting the fertilised ovum into the womb may initiate contractions which militate against implantation.

Finally, the hormonal interaction between the mother and the embryo is both critical and ill understood. In order to control the timing of reimplantation of the ovum, the woman's cycle is induced artificially with hormones, and this may result in endocrine deficiencies which could account for the failures. Nor is it clear what is the optional point at which reimplantation should be attempted.

Clearly, it is only a matter of time before someone produces a baby which began its life in laboratory glassware. That is a realistic and human goal according to Dr Edwards: "To give a couple their own child obviously needs no justification" and fears about the possible biological hazards and social implications of the technique seem on the whole unwarranted.

The misgivings voiced by the Medical Research Council on the abnormalities in embryos fertilised *in vitro* do not seem to be substantiated by the considerable body of data on animals (*Nature*, **244**, 333; 1973). The essential point is that the embryo before implantation is undifferentiated and thus almost impervious to injury. If enough cells are killed during the manipulations, the embryo dies. If it does not die, the cells regulate to produce a normal organism. There is a slight danger of triploidy if the ovum is fertilised by more than one sperm, but this can be avoided by proper control of the number of sperm used to fertilise one egg.

Most of the social, legal and ethical issues raised in connection with fertilisation *in vitro* differ little from those which arise in connection with artificial insemination or with adoption. The more horrendous imaginings of determined doomwatchers can probably be dismissed under the general proposition that it does not follow that once a thing is feasible it will necessarily or even probably be turned to undesirable ends.

These arguments, both on the feasibility and on the desirability of the technology for growing embryos *in vitro*, apply only to preimplantation development. The human uterus is still irreplaceable between six days and 24 weeks of gestation, which includes the most critical developmental period—that of differentiation, when the foetus is at its most susceptible to teratogenic influences. Not only are the problems inherent in the creation of an artificial womb during this period enormous, but none of the stated aims of current

research on human embryos *in vitro* would be served by it. The immediate aims as seen by Mr Steptoe are to overcome infertility in the 2% of couples in which it is caused by blocked oviducts, to control sex-linked disease by selecting fertilised eggs of one sex only for reimplantation, to investigate the causes of abnormality in preimplantation embryos, and to test male contraceptive drugs which can only be evaluated on the basis of their ability to prevent sperm from fertilising eggs. None of these goals would be advanced by the development at vast expense of an elaborate surrogate uterus. Not only does Mr Steptoe see no medical justification for carrying development *in vitro* further than the first few days, but the danger of abnormalities in the foetus does become serious once differentiation begins. □

Crisis in science education

from Peter Lindon

AN unhappy conjunction of two events was the origin of a conference on The Crisis in Engineering and Science Education in the West held at The University of Manchester Institute of Science and Technology (UMIST) on July 16 and 17. The two events in question were the 150th anniversary of the Institute and the decline in applications for science and engineering in the universities.

A sense of gloom and impending disaster was created from the beginning as Lord Bowden the Principal of UMIST predicted bankruptcy within 18 months for universities in the absence of any change in government policies. With student applications having dramatically fallen, and classes containing an ever increasing proportion of foreign students he wondered where the engineers and scientists to drive our essential industries would be coming from. The mechanism of manpower supply and demand seemed to be seriously at fault. From the time a child made decisions affecting the future direction of his studies until the time when he qualified, some 8–10 years had elapsed: a lag which must be an inherent cause of instability in recruitment to industry and enrolment at universities. It is precisely at the time when the need for scientists is greatest that the numbers and quality of science school teachers are eroded, the children become disillusioned with their experience of science in the schools, and the manpower supply is shut off.

Some contributors did not consider this mechanistic explanation sufficient. The social influences upon student choice were also important and Sir

A DETAILED analysis of the surface waters of the Eastern Baltic and the Gulf of Finland has now provided a theoretical basis for an experiment begun with field trials in 1969—the use of these water masses as a source of irrigation.

The first trials took place on the island of Mukku (Estonian SSR). The irrigated land yielded the “hoped-for” results, and in the spring of 1970 the research programme was started by the Irrigation Section of the V.I. Lenin All-Union Academy of Agricultural Sciences. A systematic study was made of the salinity and mineral content of the coastal waters of northern and western Estonia and of the Kihiumaa and Sarremaa. In all, 63 coastal ‘points’ were tested, samples being taken from depths of 50 cm to 1 m. In all, 664 specimens of water were analysed.

According to the report published in *Pravda* (July 25, 1974), the average salinity for the area was 1.5–2.0 g l⁻¹ (“almost fit for drinking”—a not surprising result, since the low salinity of the Baltic is a well known phenomenon, particularly as regards the 30–50 cm and 50–60 cm layers). Also in 1970, field tests

Sea water for irrigation

by our Soviet Correspondent

were begun on three collective farms having contrasting soils (sandy, argillaceous and soddy-calcareous), using crops of perennial grass, barley, potatoes, swedes, early and late cabbage, table beet, cucumbers and so on. During the four years of the tests, good results have been obtained with pasture grasses, barley and a number of vegetables. Subsequent soil tests indicated the introduction of “a fairly considerable quantity” of dissolved mineral salts into the soil; in particular, after one summer of irrigation with sea water, the sodium content of the arable soil of the “Linnamee” state farm (of soddy-calcareous type) rose from 4–10 mg per 100 g soil to 30 mg per 100 g soil. In 1971–73, further tests were carried out to determine the effect of the increased salinity on the soil microflora.

According to the *Pravda* report, which is signed by no less a person than O. Valing, Chairman of the State Com-

mittee of the Council of Ministers of the Estonian SSR on Land Reclamation and Water Economy, the results indicate that, “with a proper choice of crops and agricultural technology”, the use of sea water in irrigation can prove an important adjunct to Estonian agriculture. Yet some facts, which he calls “curious” seem to indicate the need for caution in assessing the nutritional aspects of these results. Thus barley grows taller and gives a heavier grain yield, when grown on sea water, but the protein content is “somewhat” lower. In the case of cabbage and beet, the sugar content of the sea water crop is higher. And the presentation of the report in *Pravda*, on page 2, which is normally reserved for “party” news (science reports normally are found on page 3 or page 6) would suggest that the original decision to use sea water might well have been of political, rather than scientific, origin. When one recalls the disastrous effect on Soviet agriculture, and Soviet science as a whole, of another such political decision—Lysenkoism—one can only await future news from the fields of Estonia with a certain caution.

Frederick Dainton, chairman of the University Grants Commission, referred to the alienation from science caused by its unacceptable relationship with power (often misused), and its lack of concern for people. The exploitation of science in the military context and the connection between industrialisation and pollution were cited as examples. Sir Frederick believed that science should be taught in the universities as a humanity: not as an instrument of control over the environment, but as a subject of interest for enquiring minds.

It was reassuring to find that Britain is not alone in experiencing difficulties, the most frequently recurring theme being the effects of inflation which militate so strongly against educational interests. Relief from the prevailing atmosphere of doom was given by Dr W. B. Lewis in describing changes in science at Canadian universities. Here, one felt, was a country with security in its possession of large natural resources and confidence in its future. Despite earlier predictions that the need for scientists would decline, the numbers of graduates and PhDs had increased enormously in 1973 and all were now in relevant employment. Asked what had made such changes possible, Dr Lewis stressed the prime importance of cheap energy which in Canada was not simply derived from hydroelectric sources. The advanced energy programme was capable of producing electricity even more cheaply

than from water power.

Dr J. B. Adams of CRN believed the qualities required of graduates were job flexibility and the abilities to plan, budget and acquire new technologies. He praised the breadth of approach found in general applied physics degrees and made the interesting observation that 40% of the engineers in his organisation were in fact physics graduates. The point was taken up by Professor H. B. G. Casimir, the President of the Royal Netherlands Academy of Sciences and Letters who believed that the only purpose of specialisation was to inculcate the ability to specialise; the specific subject was only of secondary importance. The three year degree in England was too short to make specialisation within it a sound proposition and he suggested that industry in this country should be prepared to recruit far more PhDs.

Sir Frederick Dainton also had some harsh things to say about specialisation in the first degree. A curriculum based on professional requirements was the easy way out for university teachers who were subject specialists themselves. Yet the factual and professional content of a degree was ephemeral. What was needed was the ability to think logically and transmit ideas clearly. Science should be taught in a spirit of enquiry and more time should be devoted by faculty to reflective consideration of their subjects and the development of discovery-based learning techniques, instead of trivial research.

Crisis is Greek for decision. Predictably the conference did not produce one, though it did illuminate some of the underlying problems of university science. With issues of such complexity and gravity one wished the organisers had provided more opportunity for discussion in smaller groups. Half-hour discussions with 450 people all facing in the same direction rarely produce anything of substance. And what of the school-teachers, invited in large numbers yet unrepresented by speakers? They work amongst shifting sands; the science departments get poorer recruitment every year and the competition from what they see as undemanding soft options gets fiercer. At a time when even previously highly selective university departments are touting for undergraduates in the schools they needed some guidance on whether to try and stimulate schoolchildren to take up science or steer them away from it. None of the speakers, one felt, took this section of the audience very seriously.

What did emerge was the fundamental need to recover the ability to plan in the long term. Only in this way can there be orderly development and the maintaining of morale. Inflation has negated planning, and if it cannot be cured we must at least learn to live with it more successfully. Meanwhile we seem confined to the world of Kafka's aphorism: “There is an end but no way; what we call the way is shilly-shallying”. □

Patrick Blackett . . .

an appreciation by Sir Edward Bullard

PATRICK BLACKETT, who died on July 13, was I suppose, the most versatile and the best loved physicist of his generation. His achievement was also without rival. Few of his friends had seen much of him during the past two years, but the sense of loss is, for me at any rate, unique. When J. J. Thomson and Rutherford died, it was sad and it was the end of an era, but their work was done and they had not, in the same degree, the wide ranging interest or the personal concern or kindness that were so characteristic of Blackett and which lasted unabated into old age.

Blackett was born in November 1897, the son of a stockbroker. At an early age he went to the Royal Naval College at Osborne and then to Dartmouth and to sea at the beginning of the 1914-18 war.

After the war he was sent to Cambridge by the Navy and soon decided that he did not want to return to the service. He once told me how, after this difficult decision, he felt as if a great weight had been lifted. He had all his life, a great affection for the Navy and a liking for an active life, but he felt he needed a wider field and one where the conventions as to what it was suitable to say and do were less restrictive.

I do not know exactly how he transformed himself from a naval officer to a research worker in the Cavendish, there is no mention in *Who's Who* of his taking a BA. He never attempted to take a PhD and when teased about accepting a peerage, replied that at any rate he had remained Mr Blackett until after he retired (this was not strictly true as he had a large number of honorary doctorates). He soon obtained striking results in the Cavendish planning of the postwar development of an automatic cloud chamber. C. T. R. Wilson, who first devised the cloud chamber before the war, was a slow-working perfectionist; Blackett was willing to take tens of thousands of photographs of hundreds of thousands of tracks if the problem needed that many. In 1925 he succeeded in photographing the emission of a proton from ^{14}N in a collision with an α particle. These famous photographs have adorned almost every text book of nuclear physics for the past fifty years.

The work with the cloud chamber led to the discovery of the positive electron in 1933 and to the study of cosmic rays by a counter-controlled chamber. This work brought out Blackett's remarkable facility in instrument

design. He could use physical theory to design a piece of equipment and then draw it, make it and get it to work. I have known nobody who possessed this combination of talents in the degree that he did. It is a major theme in his scientific work and can be seen in the bomb-sight he designed at Farnborough and in the magnetometer which he and his students used so effectively in the 1950s.

He was not entirely at ease in Cambridge or in the Cavendish. He felt that Rutherford gave a disproportionate share of support and funds to Kapitza and, perhaps, that his own left wing politics did not fit well in the still feudal-Victorian environment of Cambridge. He left for Birkbeck College in 1933, where he continued his work on cosmic rays, and then moved to Manchester in 1937. At this time he became involved in the controversies concerning the air defence of Great Britain and the relative importance of radar and other methods of detection. As a member of Tizard's Air Defence Committee he played an important part in ensuring that the essential stations were working when they were needed in 1940.

Soon after the outbreak of war he was at Farnborough; from there he moved to Coastal Command. There, and later at the Admiralty, he and E. J. Williams essentially invented operational research. He thought of it as the study of what actually happens as opposed to what is supposed or desired to happen. It was work that suited him; it involved not only intelligence and ingenuity but firmness,

persuasiveness and a commanding personality. The effect on the U-boat war was of great importance.

In the course of his work at the Admiralty he became convinced of the ineffectiveness of the area bombing of cities. After the war this argument became connected with questions of nuclear strategy. He, perhaps unwisely, said that the idea of winning a war by the wholesale destruction of cities and the slaughter of civilians was an Anglo-American innovation and was not shared by the Germans or the Russians. This argument culminated in his arrest by a sheriff in some city in the Southern United States where his plane had made a refuelling stop on the way from Mexico to Canada (the sheriff was very civil and took him to his own house and not to jail).

In the last four months of the war Blackett became deeply involved in the planning of the postwar development of science, the rapidity of the subsequent development is in large measure due to him. He returned to Manchester in 1945 and started on a completely new line of work. He investigated a possible relation between rotation and magnetisation and, when this failed as a theory of the Earth's magnetic field, turned to the study of rock magnetism. The part that this work played in the modern developments of geological theory cannot be described here.

In the Attlee administration he was regarded as too far to the left to be an acceptable advisor or member of the government. In Mr Wilson's first administration he played a large part in the setting up and conduct of the Ministry of Technology. He was a member of many official and unofficial committees, his work as Chairman of the Council of the Department of Scientific and Industrial Research (DSIR) in 1955-60 was of particular importance for the support of science in the universities.

The last time I saw Blackett I remarked that his portrait at the Royal Society made him look very serious. He replied: "But I am a very serious man". He was; he minded about the things he considered important, he thought deeply about them and held his views firmly. This could have made him tiresome and a bore, but it didn't: he was wonderfully intelligent, charming, fun to be with, dignified and handsome. There was no one like him. He had every kind of honour; the Presidency of the Royal Society, a Nobel Prize, a peerage, all the medals and honorary doctorates a man could ask for, membership of the American, French and Russian Academies and many more. To add to all this he was married to one of the most delightful women in the world who did much to prevent him from becoming too serious.

correspondence

Academics in Chile

SIR,—As signatories with other colleagues of a letter on academic life in Chile (*Nature*, May 29) we feel it necessary to comment on Dr Eyzaguirre's answer which appeared in the issue of July 5.

Dr Eyzaguirre says our letter was inaccurate, although he concedes that academic people were killed or persecuted because of "actively" opposing the military junta or because of "denunciation by neighbours or colleagues". We would like to point out the omissions and inaccuracies we find in Dr Eyzaguirre's letter.

(1) Dr Eyzaguirre depicts Dr Allende, the legally elected president of Chile, as a "corrupt" politician whose government was responsible for "chaos and anarchy". He omits to say however, that Dr Allende's government strictly respected freedom of speech and of the press and that nobody was killed, imprisoned or persecuted because of his ideas. Another omission concerns Dr Allende's respect for the independence of the university, exemplified by the election as Rector of the University of Chile of Professor Boeninger, well known to be an opponent of the government.

(2) Dr Eyzaguirre's eulogy of the military coup ("the military struck with vigour") is shocking. He admits that some "unpleasant" excesses were committed. But nothing is said about the killings in the working class quarters (*poblaciones*), the hunting of the foreigners, the tortures and the shootings at the stadiums, and the 'purification' of the libraries followed by bonfires of 'forbidden' books. The authenticity of these events is not in doubt since they have been repeatedly denounced by non-Marxist organisations including Amnesty International, the World Council of Churches and the Conference of Chilean Catholic Bishops.

(3) The comparison that Dr Eyzaguirre draws between the nomination of military chiefs as university rectors in Chile, with the nomination, for example, of General Eisenhower as President of Columbia University would be funny if it were not so sad. In the second case, the university chose to honour an outstanding military and political personality, whereas in the first a military group was imposed on the university to ensure the rigid political control of the faculty and the students.

(4) Dr Eyzaguirre states that "whole-

sale executions of faculty and scientists have not occurred" and that "very few fell either immediately after the coup because, allegedly, were caught either shooting at soldiers, carrying arms or actively participating in the organisation of revolutionary activities". Some examples may illustrate the inaccuracy of such statement. Professors Ramirez and Peña, after being sentenced by the military to only two months in prison, were shot in the city of La Serena. Leopoldo Benitez, an architect, of the Catholic University and Victor Jara, a musician, of the Technological University were assassinated in cold blood at the Stadium Chile. Enrique Paris and Luis Sanguinetti of the University of Chile at Santiago and Michael Woodward, of Valparaiso, died while being tortured. More than ten medical doctors were shot by the junta.

(5) Dr Eyzaguirre takes as an example of the university situation the Catholic University, where no student has been expelled. He says that Admiral Swett Madge, the new Rector, was nominated with the approval of Cardinal Silva Enríquez. He omits to say that the previous Rector, Professor Fernando Castillo Velasco, also approved by the Cardinal, was dismissed by the junta, had his house ransacked and decided to leave Chile. Dr Eyzaguirre also states that only 3.5% of the Faculty was dismissed by the Rector on political grounds. He omits to say that at least four institutes (among them the Institute of Economic History and the CEREN, a centre for Chilean studies) were dismantled and all their members dismissed. He also neglects to say that Father Mauricio Hebert and six other professors were expelled from the country.

Moreover the Catholic University enrolls only 10% of the student population. Dr Eyzaguirre does not quote the number of faculty members dismissed at the University of Chile. He only tells us that the only students expelled (no figure is given here either) were those with unsatisfactory academic records. It is difficult to accept, for instance, that more than half (141 out of 254) of the first-year students in the science school, who were not allowed to re-register, were agitators or professional politicians. A final remark is necessary. When we signed the letter to *Nature* asking for help for the jobless university teachers, and teachers who were persecuted by the junta or who refused to work under a totalitarian

regime, we did not state or imply that the scientists or academics who decided to stay in Chile (among them many respected friends) were fascists. Dr Eyzaguirre says that they are "labouring under difficult circumstances which are mainly economic". We think that this is an understatement in view of the present lack of freedom and disrespect of the human rights. It is because of this that we find it so unfair that Dr Eyzaguirre should dub those who left Chile as '*gauchistes de salon*', in particular because many of them still have families in Chile and are therefore unable to answer him publicly.

Yours faithfully,

H. M. GERSCHENFELD

J. P. CHANGEUX

Paris, France

Algae as fuel

SIR,—A few words may be in order about planktonic algae cultivation as a means of harnessing solar energy, which was not mentioned in your Energy Review (*Nature*, June 21, 1974).

Algal cultivation has many advantages over plant cultivation. Whereas land for afforestation is becoming scarce, vast areas of lagoons and inland lakes are available for algal cultivation. About 1% of sunlight that falls on an area is absorbed by the plants growing there, but sunlight can diffuse through water down to a few hundred feet and so more than 1% of the sunlight can ultimately be absorbed by algae in water. Algae can grow in a variety of aquatic environments and there will be added advantages if sewage is added to the medium because the oxygen liberated by algal photosynthesis can be used by the bacteria in the medium to break down the organic matter in the sewage.

Also algae multiply fast. In large experimental ponds yields as high as 36 tons of algae per acre of pond per year have been achieved, compared with the yield of about 1 ton per acre of dry organic matter which plants yield. Thus a lake of 100 square miles can yield more than 2,000,000 tons of algae per year, which can be used as fuel in conventional thermal power stations.

Yours faithfully,

N. UMAKANTHA

Symmetry in recognition sites for proteins

WHEN nucleotide sequence analysis on RNA was beginning to gather momentum in 1965, such endeavours with even the simplest of DNA molecules were limited to preliminary skirmishes from a few optimists; but it was at this time that Bernardi entertained a model for the interaction of spleen DNase with its substrate which is now widely invoked for the reaction of many proteins with DNA. From the nature of the 3' termini of the products generated by this enzyme, which contained two identical polypeptide chains, Bernardi (*Adv. Enzym.*, **31**, 13; 1968) proposed that the subunits of the enzyme are associated about an axis of two-fold rotational symmetry. Thus alignment of this axis with a corresponding axis between two opposed -G-C- pairs in a DNA duplex ensured that a catalytic site on each enzyme subunit is appropriately positioned to make equivalent breaks in each polynucleotide chain to leave -Gp.

Interactions based on this type of model proved very attractive for the more complex nucleotide sequences found at the positions of breakage of DNA by certain restriction enzymes. Following the demonstration by Kelly and Smith (*J. molec. biol.*, **51**, 393; 1970) that nucleotide sequences at the sites of breakage of DNA by a restriction enzyme (comprising four subunits) from *Haemophilus influenzae* were bisected by an axis of two-fold rotational symmetry, such rotationally symmetrical sequences, or palindromes as they are termed in some quarters, have been found at the interaction sites for several restriction and modification enzymes: the recognition sequences so far determined are tetra, penta, or hexanucleotides, becoming degenerate thereafter.

One would anticipate that some of the more important control functions would require larger nucleotide sequences to ensure their unique recognition. It was therefore of interest to note that in the first of the larger recognition sequences to be determined, that of the interaction site for the λ *ter* system, that is, the enzyme generating mature DNA molecules from a concatenated replicative intermediate form (Weigel, Englund, Murray and Old, *Proc. natn. Acad. Sci. U.S.A.*, **70**, 1151; 1973), rotational symmetry was again apparent, but this time the base pairs that were symmetrically arranged about the axis were not in continuous sequence, but showed a broken, or hyphenated symmetry. The *lac* operator provided a further, and rather more complex, example of a sequence of nucleotides with a discontinuous symmetry about an axis through a base pair rather than between two pairs, a feature of one of the recognition sites of the restriction enzyme (Gilbert and Maxam, *Proc. natn. Acad. Sci. U.S.A.*, **70**, 3587; 1973).

Recent and current work on the structure of DNA in areas concerned with the control of gene expression is providing more examples of structures of this sort, and a fascinating picture is emerging of the rather complex way in which the macromolecules may interact. Detailed study of regulation in phage λ has been made possible by exploiting the extensive background of genetics with this phage and the availability of many deletion and mutant strains. Expression of early genes in λ begins with transcription

from two promoters, P_L and P_R , located astride the immunity region. Interaction of RNA polymerase with these promoters is prevented by interaction of the λ repressor, the C_1 gene product, with the relevant operators, O_L and O_R . Maniatis and Ptashne (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 1531; 1973) recently showed this to be a rather complex reaction involving at each promoter the stepwise addition of repressor molecules to six reiterated binding sites which were similar but not identical in nucleotide sequence. These sites, S_1 to S_6 at the two operators, ran in opposite directions towards the C_1 gene on the map of the λ chromosome. Other promoters mediate the expression of genes involved in late functions and yet another promoter dictates synthesis of repressor during the consolidation of lysogeny. The various promoters are accurately located on the map of the λ chromosome. This enabled Allet and Solem (*J. molec. Biol.*, **85**, 475; 1974), through a comparative analysis (by gel electrophoresis) of the fragments obtained by digestion of DNA from λ and a variety of deletion strains with several restriction endonucleases, to isolate fragments of DNA containing only one promoter; this work considerably enhances opportunities for biochemical studies of transcription *in vitro*.

Of more immediate interest, however, was their observation, made also by Maurer, Maniatis and Ptashne (*Nature*, **249**, 221; 1974), that DNA from the mutants *sex1* and *sex3* which are defective in the left promoters, P_L , when digested with restriction endonuclease R.HindII did not give the fragments that had been shown to result from breakage within O_L , the left operator, but instead gave a larger fragment equivalent in size to the two missing fragments. A corresponding mutant, *x13*, inactivating the right promoter, P_R , did not, however, affect the action of R.HindII at its site located within O_R . Both groups of workers then showed that the sites for R.HindII located within both O_L and O_R were protected from digestion by the binding of RNA polymerase, which established that operator and promoter sequences are identical or overlapping.

The occurrence of the R.HindII recognition sequence, -G-T-Y-R-A-C-, within the operators O_L and O_R has now been exploited by Maniatis, Ptashne, Barrell and Donelson, (see page 394 of this issue of *Nature*) for determination of a significant piece of nucleotide sequence in this important area of the λ DNA molecule. The R.HindII fragments flanking the break point in O_L , which occurs between sites S_1 and S_2 , are about 320 nucleotides long to the left and about 1,125 nucleotides long to the right. The longer of these two fragments was prepared in quantity (using gel electrophoresis), denatured, and then annealed to equimolar quantities of the purified *l*-strand of λ DNA. This gave a molecule that was both a primer and template for polymerase reactions, so that the 3' terminus of the annealed strand of 1,125 fragment could be extended by condensation of nucleoside 5'-triphosphates with DNA polymerase. Using Berg's adaptation of this reaction to substitute incorporation of a ribonucleotide for one of the deoxyribonucleotides, Maniatis *et al.* made products with rC or rG substituted (in separate reactions) to facilitate analysis of 32 P-labelled extensions of the 1,125 fragment.

• Analysis of the products of these syntheses were simplified by first cleaving with the HindII restriction enzyme and fractionation of the mixture of oligonucleotides (which had

a common 5' terminus but varied in their 3' terminus because of asynchronous synthesis) by the homochromotographic methods exploited so well by Sanger and his colleagues. Further cleavage of these oligonucleotides with pancreatic or ribonuclease T₁, followed by fractionation of the products and analysis of them by partial exonuclease digestion (to give further products that could be identified from their behaviour on two-dimensional fractionation systems), finally led to the proposal of a sequence of 59 nucleotides from the HindII site in *O_L* which extends into the region of *N* gene transcription. Since this sequence originated at the HindII site within *O_L* which is protected by RNA polymerase binding, it limits the distance separating bound RNA polymerase from the T-A-G with which *N* gene transcription begins to 33 base pairs and so reinforces the challenge to the suggestion made two years ago that the left promoter and start of transcription are appreciably separated.

Within this region of 33 base pairs to the left of the HindII site are three axes of two-fold rotational symmetry each involving hyphenated distribution of the symmetrically arranged 14 to 16 bases. All three blocks of symmetrical sequence seem to lie within the region covered by the repressor and it is intriguing to contemplate that these interdigitating symmetries are the recognition sequences for different regulatory proteins (including the *tof* (or *cro*) gene product to regulate leftward transcription). One can only agree with the authors that analysis of the structure of the remaining sites in the operators and localisation of regulatory mutations should provide a clearer understanding of the significance of these symmetries.

Of no less interest will be the elucidation of the structure of other promoters (in addition to that of the phage fd promoters determined recently by Seeburg and Schaller),

because Allet Roberts Gesteland and Solem (*Nature* **429**, 217; 1974) have shown that the HindII recognition sequence occurs in several, but not all, promoters in phages λ and T7 as well as in the mammalian viruses SV40 and adeno2. Extension of the work on the *lac* operator (Gilbert, Maizels and Maxam, *Cold Spring Harb. Symp. quant. Biol.*, **38**, 845; 1973) has now identified the position of several mutations in this sequence and these occur in both symmetrical and non-symmetrically arranged bases. With this system (and others) analyses of the regions of the enzyme involved in the interaction will also be relevant to the meaning of symmetry and here, production of active *lac* repressors that are covalently fused to β -galactosidase (Müller-Hill and Kania, *Nature*, **249**, 561; 1974) will help to define necessary regions of the repressor. Detailed analysis of the *L*-arabinose operon, which is under positive control, is also in prospect following the recent studies of araC protein binding to the ara operator by Wilcox, Clemetson, Cleary and Englesberg (*J. molec. Biol.*, **85**, 589; 1974). Much remains to interest those who do not believe that prokaryotic molecular biology is finished.

From a correspondent

Russian cosmology

It has been a recurring preoccupation among cosmologists to establish connections between the microscopic and macroscopic of the Universe. Eddington attempted to discover a fundamental relationship between atomic and cosmological systems, and other workers still continue to pursue this possibility. Among these workers is the nuclear physicist Andrei Sakharov, the same individual who has recently achieved world renown as a leading Soviet dissident. Sakharov and his colleagues, notably the eminent astro-

Sitting in a hot seat

THE spectacular nature of volcanic eruptions has long attracted scientific observers. As far back as 79 AD Pliny documented the eruption of Vesuvius and the accompanying destruction of Pompeii and Herculaneum, and by the beginning of this century, when Frank Perret was travelling the world compiling a chronicle of volcanic eruptions, volcanology had become well established as a science.

Today, there are volcanic observatories in a large number of places throughout the world. Many, including those on Vesuvius, and in Japan, Hawaii and Soufrière in the West Indies, use extremely sophisticated techniques. Seismic networks record tell-tale cycles of seismic activity, and geodetic measurements involve the use of lasers to detect the dilations of a volcano, which presage serious eruptions.

Volcanologists are not confined to predicting the onset of eruptions. By taking records during eruptions they can determine the source and nature of a lava, which often enables them to anticipate how a particular volcano is likely to behave during future periods of activity. The prognosis may be of use to communities who wish to prepare as best they can for likely contingencies. In that respect, the measurement of such parameters as the viscosity, effusion rates and temperature of a lava, and the detailed chemical and mineralogical analyses are all important. On page 385 of this edition of *Nature* an Anglo-Italian team of volcanologists report their observations of a recent eruption of Mount Etna in Sicily.

Most volcanologists are quick to admit that, unfortunately, there is very little that can be done to safeguard livelihoods and property. On Hawaii, always threatened by mobile basaltic magmas, there have been attempts to

chill advancing lavas, but these measures usually prove to be ineffective. The Hawaiians have, however, successfully diverted lava from its course with bombs; but elsewhere, in densely populated areas, that action may be a palliative which merely shifts the problem from one community to another.

There are few precautions that can be taken against the threat of ash falls, as evidenced on Heimaey in Iceland in 1973. Then, during the eruption of Eldfell, homes and land were completely blanketed by vast volumes of ash within a few days. And against the worst type of volcanic hazard—*nuées ardentes*—there is absolutely nothing that can be done. *Nuées ardentes* are hot avalanches of loose, explosive lava lubricated by constantly expanding gases and vapours. Because of their internal energy, they sweep down the flanks of volcanoes with tremendous speed, often flowing uphill and across barriers, burning all in their paths. In 1902 a *nuée ardente* swept down Mont Pele, on Martinique, and, within the space of a few minutes, annihilated the 30,000 inhabitants of the port of St Pierre.

Inevitably, volcanoes still retain many unknown characteristics, and continue to behave unpredictably. Volcanologists on Vesuvius are becoming "very worried". That volcano has a long history of particularly unpleasant eruptions, and all of the indications are that it should have erupted at least twice during the past 30 years or so. Geodetic measurements show that the flanks of Vesuvius are bulging to an alarming degree. Evidently, the Vesuvian volcanologists could do worse than consider their own counsel. They might also be wise to bear in mind recent events on Etna—in 1971 the volcanic observatory on that mountain was among the first obstacles to be swept away before the advancing lava.

ALLAN PIPER

physicist Zeldovich, have been developing a theory which attempts to link the phenomenon of gravitation, which governs the motion of large scale systems, with the quantum structure of the vacuum (*Dokl. Akad. Nauk S.S.S.R.*, **771**, 70; 1967).

The modern quantum field theorist has a conception of a vacuum which differs greatly from that implied by the popular usage of the word. The absence of particles does not mean just 'empty space'. Rather one must imagine a continual interchange of energy between different forms, as 'virtual' particles of all types appear and disappear in transient fluctuations of incredibly short duration. The origin of this vacuum energy is analogous to the energy which prevents the electrons in an atom from collapsing into the nucleus.

Also in gravitation theory, empty space is rich with structure. The presence of a gravitational field is interpreted in the general theory of relativity as a curvature of space, that is, a distortion of the geometry. The stronger the gravitational field, the more the space geometry becomes distorted. The precise amount of distortion produced by a given gravitating mass (for example the Sun) is determined by the value of Newton's gravitational constant G . Although this value may be measured, it has long been a dream among physicists that Newton's constant might be derived in some way, or connected in a relationship with other, perhaps microscopic, constants of nature.

Sakharov has proposed a derivation of G based on an analogy between the vacuum and an elastic medium. In the same way that distorting the shape of a piece of rubber leads to a change in its internal energy so, Sakharov argues, a distortion of empty space by a gravitating mass leads to a change in the energy of the vacuum, as interpreted by quantum field theory. G may then be calculated as an 'elastic constant of space' from the theory of elementary particles. The expression for G given by Sakharov contains an unknown mass which corresponds to the heaviest allowed elementary particle. To get the right value for G , this mass must be about 10^{-2} g, or 10^{19} times as heavy as the proton!

Whatever the merits of this particular piece of work, the idea of appealing to elementary particle physics and quantum field theory in investigations of large gravitating systems is a fascinating one which is occupying the attention of other Soviet scientists at this time. Zeldovich had previously explored a possible connection between the quantum fluctuations of the vacuum and the existence of a cosmological constant in Einstein's field equations of general relativity. A recent paper

(*Phys. Lett.*, **50B**, 340-342; 1974) by Kobsarev, Okun and Zeldovich presents new work in the same spirit. This time, these authors turn their attention to the subject of symmetry breaking in elementary particle physics. It is well known that certain elementary particle processes violate the so-called CP symmetry; that is, symmetry under charge reversal and space (mirror) reflection. The Russians have applied a simple model due to T. D. Lee for CP violation to the subject of cosmology. The essence of their article is that, because of CP violation the vacuum acquires a domain structure loosely similar to that of a ferromagnet, adjacent domains differing by the sign of the CP violation. These domains form during the early stages (at about 10^{-5} s) of the hot big-bang at the beginning of the Universe, and arise (at random) because of the existence of causally separated regions which always occur in this type of model universe. Roughly speaking, each domain wants to form with the same sign of CP violation throughout, but it cannot know the sign in adjacent domains. As the universe expands, so do the domains.

The behaviour of a universe filled with such domains is drastically different from the conventional models. The authors consider the dynamics of the system to be dominated by the behaviour of the domain walls, which are in a state of tension, and have the peculiar equation $p = -2/3 \epsilon$ connecting the pressure p and the energy density ϵ . This relation leads to a model universe which expands like t^2 , that is, accelerates to unlimited expansion, even in the case of the cosmological constant being zero, in contrast to the conventional models of this class which always decelerate as they expand.

As the authors point out, such a rapid expansion is not really consistent with present density observations of the Universe. More seriously, the gravitational field of the domain walls would be likely to destroy the observed isotropy of the cosmic microwave background radiation. For this reason, it is suggested that a mechanism must exist for removing the domain walls after about 10^{11} s. One possible such mechanism would be to connect the sign of CP violation with the expansion of the Universe, perhaps along the lines of the work by Ne'eman (*Int. J. theor. Phys.*, **3**, 1; 1970).

It is hard to know how seriously cosmological models of this type should be taken. As a general principle, however, it is important to appreciate that as accelerating machines become ever more expensive to build, the testing of theories in elementary particle physics by constructing cosmological models is becoming progressively more attractive.

P. C. W. DAVIES

Floating on high

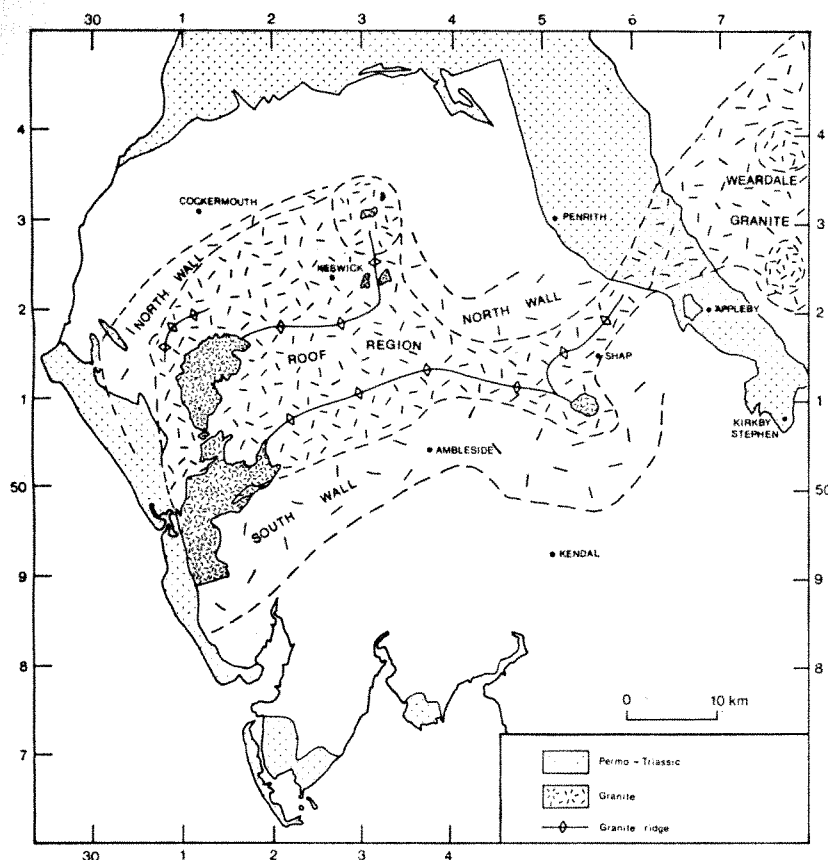

from J. Sutton

SEEN from the air—a journey between Glasgow and London on a fine day provides the opportunity—the mountainous Lake District contrasts strikingly with the surrounding subdued landscape. This contrast has its roots in a long geological history which Bott has recently investigated (*J. geol. Soc. Lond.*, **130**, 309-331; 1974).

The Lake District, like many other areas of high ground in Britain, is underlain by Palaeozoic metamorphic rocks; the surrounding lower ground is underlain by younger rocks, though these too rest on a buried Palaeozoic basement. This situation, a deep Palaeozoic basement below a younger cover, can be matched elsewhere in and around Britain—below the Cheshire Plain for example.

During the past 250 million years, much of the crust of the British Isles has been broken into a mosaic of blocks some tens of kilometres across. Some of these have moved upwards, and others have gone down. Why should this be? That is a question which Bott has made his speciality in recent years. He has already shown that south-west England and the northern Pennines are underlain by granites which are larger than their surface exposures alone suggest. He has now demonstrated that the Lake District is in the same condition. Bott has established that the Lake District is marked by a belt of relatively low Bouguer anomalies; in other words, some rock near the surface is unusually light compared with its neighbours. Particularly low gravity values occur over the isolated granites which reach the surface at Eskdale, Shap and Skiddaw. Bott attributes the anomaly to a concealed granite, connecting these outcrops at depth, and extending for some 80 km, at least as far east as Weardale. The granite lies high in the crust, it is suggested, within the top 10 km, and thus forms another example of a high level Caledonian intrusion—it was intruded in early Devonian times, nearly 400 Myr ago.

These results bear on two distinct, but related, geological questions. In the first place the work brings out the position of outline of another Caledonian granite, adding to the number known already in north-west Britain. As Shackleton pointed out in the discussion of the article, the nature of the upper surface of the Lakeland granite presents a problem. Why is it that the levels to which the granite rose were rather uniform over quite a wide area? As more geophysical evidence on the shape and depth of other buried Palaeozoic granites comes to hand this

Sketch map showing the inferred distribution of unexposed and exposed granite beneath north-west England. The map shows the roof and wall regions of the postulated Lake District batholith, the main granite ridges being indicated by the gravity anomalies and the postulated connection to the Weardale granite (from Bott, *J. geol. Soc. Lond.*, **130**, 319; 1974).

problem might become better understood.

Such information will help with the second question—does the distribution of low density granities, high in the crust, play a critical part in determining which blocks of Palaeozoic crust act as bouyant upward-moving blocks and which subside to be buried by sediments? So much of the wealth of this country in the form of coal or oil is present in sedimentary basins formed since Carboniferous times above a Palaeozoic floor, that an understanding of this question would have a practical as well as an academic value.

Bott shows that in the Lake District the density contrast between the granite and the country rocks would cause a gravity deficiency of magnitude $1 \times 10^{18} \text{g}$, and finds that this is of the same order as the total mass of the Lake District rocks above sea level, which he computes as $1.49 \times 10^{18} \text{g}$. These calculations support the hypothesis which Bott has already applied at Dartmoor and in the Northern Pennines, which proposes that low density granites high in the crust can account for blocks of elevated country. There is good stratigraphical evidence that the mountainous block seen in the Lake District today, has been rising and shedding detritus at least since the

Carboniferous. In other words, what is now the Lake District has been bouyant since the time the granite was intruded. An interesting experiment now would be to attempt to find out whether the depressed portions of Palaeozoic crust which underlie sedimentary basins lack low density intrusions. Such a discovery would give further support to Bott's hypothesis.

Radar mapping of the Moon

from David W. Hughes

WHY bother to look at the Moon with radar? The answer is quite simple. Whereas Earth-based telescopes can, with the best conditions of optical viewing, give a lunar surface resolution of a few hundred metres, returned radar echoes can yield the distribution of objects with sizes around the radar wavelength—typically in the 4–150 cm region. This degree of fine resolution can also be obtained using orbital and lunar surface photographic techniques but only at considerable expense.

Now a resolution of 1 arc s can be obtained at optical wavelengths, even using small telescopes. Using simple radar with currently available aerial beamwidths, and straightforward

attempts at angular resolution, a value of 4 arc min is obtained, which when compared with the 30 arc min diameter of the lunar disk shows that only very large scale features can be picked out.

The Delay-Doppler mapping technique gets over this problem. As the Moon is rigid, a known motion of the whole body will enable the motion of each surface feature to be calculated. This movement produces a Doppler shift in the echo, and by high resolution frequency analysis selection can be made of the component of the echo originating from a known strip on the lunar surface; this strip is parallel to the apparent axis of rotation. Range analysis enables a circular annulus, centred on the sub-radar point, to be selected. A combination of both techniques isolates two scattering areas, only 10^{-5} , or less, of the total visible lunar surface. The ambiguity produced by having two areas is overcome by making the separation between these areas greater than the angular half power beam width of the radar antenna.

The resolution problem can be thought of in another way. Consider the radar wavefront hitting the Earth. The apparent rotation of the Moon sweeps this wavefront past the antenna and so sequential sampling of the received signal produces results equivalent to sampling simultaneously the original waveform over the region swept out by the antenna during the time interval of observation. Thus, large observing apertures can be synthesised, producing greatly improved angular resolution; in fact the degree of resolution is at present only limited by system stability and data processing constraints.

The observed distribution of echo power with delay and Doppler frequency can be thought of as having two components. The first is coherent and quasispecular, caused by reflections from the relatively smooth undulating lunar surface. This component is polarised just like the incident radar beam. The second component is incoherent, diffuse and largely unpolarised, and originates from wavelength sized structures, thought to be mainly rocks on or near the surface. Careful normalisation of the returned echo enables surface tilt to be eliminated as a source of scattering difference between different regions of the lunar surface. The remaining enhancement of radar echoes is then a measure of the rock population (the rocks detected would have sizes between one quarter wavelength and about 10 wavelengths; rocks also give signals provided they are not buried deeper than about 20 wavelengths).

The results of high resolution radar mapping, at 3.8 cm and 70 cm, of the lunar surface facing the Earth are given in a series of three articles in a recent edition of *The Moon* (10, 1974). The

radar window is limited by the absorption by water and oxygen molecules in the Earth's atmosphere; 70 cm is in the centre of this window, and 3.8 cm is close to the edge. The 3.8 cm observations had a resolution of 2 km, and the 70 cm observations had an aerial resolution of 25 km², which is twenty times better than previous results. The results were obtained by Pettengill, Zisk and Catuna at the Haystack Observatory, Massachusetts Institute of Technology and by Thompson at the National Astronomy and Ionosphere Centre, Arecibo, Puerto Rico.

By comparing radar maps with Lunar Orbiter photographs of the same area three basic radar features can be distinguished. They are well defined, named craters, very small un-named craters and, finally, radar anomalies with no apparent optical counterpart. There seems to be an anomalously strong radar return from small craters, which is not necessarily correlated with their apparent size or optical albedo.

The authors conclude that the craters which give large echoes are young, with sharp contours and steep inner slopes. The rough inner surfaces are tilted steeply towards the Earth-based radar, leading to depolarisation of the returned signal. These craters also have excess rock populations caused by the excavation of large quantities of bedrock during formation and subsequent depositions around the crater in a strew field many kilometres across. Meteoric erosion slowly removes the hallow, grinds the rock into fine grain debris and produces a shallow subdued topography, thus reducing the echo strength to the average lunar value. Most of the enhanced echo craters are thought to be Copernican in age. It is concluded that spallation of rocks caused by impacts with sufficient energy to fracture centimetre sized and larger rocks, is a common lunar phenomenon.

One radar anomaly found in the Kepler region is thought to be formed by a large clod of material which was thrown out with the ray material when Kepler was formed. The 70 cm data, with the help of 'ground truth' observations at Apollo landing sites, has enabled the percentage roughness of the lunar surface to be calculated.

Not only are the youngest craters on the Moon strong radar scatterers; they also have enhanced eclipse temperatures (that is infrared anomalies—elevated temperatures which certain areas maintain during the umbral phase of an eclipse). Correlations between radar and infrared maps show that these 'hot spots' can be explained by the thermal behaviour of surface rocks, provided these are 10 cm or larger in size and are greater in number on the surface than at the Surveyor 1 and 3 landing sites.

Analysts celebrate

from T. S. West

THE celebrations of the centenary of the Society for Analytical Chemistry which were held from July 16 to 19, began with a special 'historical' meeting at the Royal Institution in London at which fraternal greetings from 30 kindred societies were presented—most of them from overseas. The scrolls and presentations are now on display for 6 months at the special exhibition "You and Your Analytical Chemist" at the Science Museum in South Kensington.

Sir Alan Hodgkin, president of the Royal Society, described the founding of the SAC on August 7, 1874 in the City Terminus Hotel, Cannon Street and traced the events that had been set in motion by the actions of Professor Theophilus Redwood and his group on that day. The society, which had formerly existed as The Society of Public Analysts (1874-1907), then as The Society of Public Analysts and

Other Analytical Chemists (1907-1953), had a membership of 2,000 in 1972 when it had undertaken a joint role with the new amalgamated Chemical Society as the kernel of the Chemical Society's Analytical Division with a membership, in 1974, of 5,000.

Dr G. W. C. Milner, the centennial president of the SAC, highlighted some of the events of the past hundred years and looked forward to the future. The society, with only 2,000 members in its hundredth year obviously stood at the crossroads and was faced with a decision to continue, as before, independently or to amalgamate fully with three other British sister chemical societies (the former Chemical Society, The Faraday Society and the Royal Institute of Chemistry) and become the Analytical Division of the (new) Chemical Society. The presence of more than 3,000 additional 'first choice' members in the Analytical Division of the Chemical Society had influenced the council's decision to recommend full unification to the members at a referendum to be held later this year.

Nitrogen aggregates in diamond

from John Walker

IT has been known for many years that some diamonds contain precipitates ('platelets') on (100) crystal planes which give rise to anomalous features ('spikes') in Laue X-ray photographs. When Kaiser and Bond (*Phys. Rev.*, **115**, 857; 1959) found by mass spectrometry that these diamonds also contained large quantities of nitrogen impurity, it was natural to assume that it was contained in the platelets. Shortly afterwards, in 1962, the platelets were observed in transmission electron microscopy. Everything fitted and everybody was happy.

Six years later Sobolev *et al.* (*Sov. Phys. Doklady*, **12**, 665; 1968) upset the applecart by discovering that the X-ray spikes did not correlate with the total nitrogen content of diamonds, which meant that the platelets contained little if any nitrogen. This raises two questions. Of what are the platelets made and where is the nitrogen? The first question was and is still open, but the second could be partially answered. Electron microscopy can detect features only a few Ångströms in diameter, and since none had been observed the nitrogen aggregates must be very small—effectively point defects. This deduction has now been confirmed by Turk and Klemens (*Phys. Rev. B*, **9**, 4422; 1974) using thermal conductivity.

Any imperfections in a crystal scatter the phonons (lattice vibrations) and decrease its thermal conductivity. The amount of scattering depends on how big the scattering centres are relative to the phonon wavelength, and since that changes with temperature, so does the scattering. Hence the variation of thermal conductivity with temperature contains information on the size and concentration of defects in a crystal. What Turk and Klemens have done is to calculate the scattering effect of platelets and point defects, and fit their results to the experimental thermal conductivity data of other workers. They deduce for one diamond that only 3% of the nitrogen it contains is in platelets: the rest is in small clusters of eight nitrogen atoms. They have therefore confirmed the conclusions of Sobolev *et al.* using a totally different technique, and the eight-atom cluster would probably be too small to see in the electron microscope, as was expected.

One would now hope that Turk and Klemens could extend their work to many more specimens: for example infrared and visible spectroscopy suggests that there are not one but at least three types of small nitrogen cluster (the so-called N₃, A and B defects) in some diamonds. It would be interesting to see if they could be distinguished and their sizes measured.

Hierarchy of behaviours in a gastropod

from Marian Dawkins
Animal Behaviour Correspondent

ANIMALS in their natural environments are often exposed to mixed, even contradictory sensory inputs. It may be impossible for an animal to react to all these inputs at once, as the behaviours involved may actually be mutually incompatible; for example, an animal cannot both approach and withdraw from an object at the same time. One of the interesting features of the evolution of the behaviour of animals has therefore been the development of a system of priorities whereby these conflicts are resolved in such a way that the survival and reproduction of the animal is most likely. This often takes the form of animals in conflict situations performing certain behavioural responses to the partial or complete exclusion of others, and in this sense the animals can be said to have a hierarchy of behaviours.

Marine molluscs such as *Pleurobranchaea* have already proved to be extremely fruitful material for understanding the neurophysiological bases of many behaviours and it is therefore promising for the discovery of the neural basis of such a behavioural priority system that their behaviour has been found to be organised into an explicit priority sequence. Davis, Mpitsos and Pinneo (*J. comp. Physiol.*, **90**, 207-224; 225-243; 1974) have found that in this species, which is a carnivorous gastropod, feeding is a relatively dominant behaviour and takes precedence over most other behaviours. They presented animals with stimuli which released two different behaviours: in one experiment they gave a food stimulus to animals which had been turned upside down. Instead of showing their usual almost immediate righting behaviour, the animals stayed on their backs and ate, often for up to an hour. Feeding also dominated head withdrawal and mating, and Davis *et al.* argue that the adaptive significance of this is that *Pleurobranchaea* is a carnivore with a sporadic and rather limited food supply and so opportunities for feeding being rather scarce, feeding requires immediate and decisive interruption of all other behaviours.

Interestingly, there are some situations in which feeding is not given top priority. Davis *et al.* found that this behaviour is hormonally suppressed during egg laying; presumably this is an adaptation to ensure that the animals do not eat their own eggs. Even higher in the hierarchy than egg laying

is the escape swimming response to avoid predators. This can interrupt any other behavioural act and so ensures that the animals survive to perform their other behaviours at times when no danger threatens.

The organisation of behaviours into hierarchies of adaptive priorities, Davis *et al.* suggest, may be a unifying theme for a diversity of complex behavioural phenomena in many animals, and to have discovered one in a mollusc with a simple analysable nervous system encourages the analysis of this phenomenon at the level of the single nerve cell.

Can partons be saved?

from David J. Miller

THE most eagerly anticipated parts of the International Conference on High Energy Physics, held in London during the first ten days of July, were the sessions devoted to electron-positron annihilation. Most delegates had already heard of the surprising results obtained by physicists at Stanford California, and at Cambridge Massachusetts, concerning the rate of production of strongly interacting particles (hadrons). The conference gave the Stanford group a chance to report their results in detail, and to be closely cross-questioned about them. It also gave theorists their first chance to try and explain what had been discovered.

The Stanford and Cambridge experiments involved the storage of electron and positron beams of up to 2.6 GeV. The stored beams were brought together, twice per circuit in the Stanford SPEAR ring, and allowed to make head-on collisions. There was an array of scintillation counters and spark chambers around each intersection region, and it was possible to recognise whether outgoing charged tracks were caused by electrons, muons or hadrons. Electrons produce characteristic showers when they pass through dense material; hadrons are totally absorbed by a foot or so of steel, because of their strong interactions; muons are more penetrating than any other charged particles. The American results confirmed findings, at Frascati in Italy, Orsay in France and at Novosibirsk in Russia, that electron-positron scattering has all the properties predicted for it by the well established theory of quantum-electrodynamics. Elastic scattering, the production of muon pairs and the production of photon pairs all behaved exactly according to theory. The surprise came in the rate of hadron production. Up to a beam energy of about 1.5 GeV at Frascati, this rate falls off in the same way as

the production of muon pairs. But in going from a total electron-positron energy of 3 GeV (that is 1.5 GeV electrons plus 1.5 GeV positrons, meeting head on) to the 5.2 GeV available at Stanford and Cambridge, the rate of hadron production levelled off and stayed roughly constant. This is not a contradiction of quantum electrodynamics, but it is very surprising.

Theorists had been quite happy with the behaviour of hadron production at the lower energies. They had compared it with muon production, and worked out a theory in which the electron and positron annihilated by first of all creating a massive single photon. This process is formally just the reverse of electron-positron pair production by a photon close to an atomic nucleus. The heavy photon could then generate a muon pair, one positive and one negative, or it might generate a 'parton' pair in just the same way. Partons are hypothetical objects which are supposed to be the building blocks from which the hadrons are made—just as the hadrons themselves are the building blocks for nuclei.

The parton theories have been supported by a number of recent experiments where leptons (electrons, muons or neutrinos) are scattered from nucleons (protons or neutrons, free or in nuclei). These so called deep inelastic scattering experiments have been done with electrons at a number of laboratories, including Stanford, and with neutrinos in the Gargamelle bubble chamber at CERN, Geneva. The results are in some ways similar to Geiger and Marsden's alpha particle scattering experiment, which led Rutherford in 1911 to postulate a small point nucleus in each atom. The angular distribution in deep inelastic lepton scattering from a proton is just what would be expected if protons had very small constituents. There is even evidence to suggest that these constituents or partons may have the same charge and spin as the quarks, which were postulated in 1973 by Gell-Mann and Zweig to explain the regularities in the spectrum of the resonances of the strongly interacting particles. The quarks are the most intuitively straightforward way of building up hadrons which fit into the 'SU(3)' symmetry scheme.

In 'parton pair production', by a single photon from electron-positron annihilation, it was suggested that the partons would first be produced, and would then 'clothe' themselves with other partons, spontaneously generated from the vacuum, forming hadrons of the kind which can be observed. Quarks, or any other form of parton, have never been observed, and perhaps cannot exist as free observable par-

ticles. Despite the complications of the 'clothing' process, the basic rate for hadron production by means of parton pair production should have the same dependence on the overall electron-positron energy as does muon pair production.

The new SPEAR and Cambridge results disagree with this. Muon production falls as the energy increases, but hadron production levels off. This directly contradicts simple parton theories. More than seventy theoretical papers were submitted to the conference, attempting to explain this effect in one way or another. Some suggest that the levelling off in hadron production is a temporary phenomenon at 'medium energies', and the high energy decrease has yet to begin. Others claim that massive 'charmed' particles are being produced (see *Nature*, **250**, 186; 1974 for a discussion of other contexts where 'charm' has been invoked), and the reaction rate is rising as more charmed final states become available. Other theorists have pointed out that the levelling off in hadron production is "more parton-like than partons". If the hadrons were not formed by production of pairs of point-like constituents, then the hadron production should fall faster than the rate of muon production. This suggests that some totally new phenomenon is being seen in electron-positron annihilation.

To test these theories it will be necessary to collect data at higher energies, and to make more detailed studies of the hadrons in the final state. The SPEAR ring is already being modified to give higher beam energies, but it seems likely that a much larger increase in energy will be needed to answer all the questions raised by the new data. British physicists could have a major part to play in the development of these studies. To reach the higher energies, new machines must be built, and Britain's long-term plans in this direction are as far advanced as those of any other nation. The Science Research Council should decide this year whether to build its EPIC storage rings which will have 14 GeV electrons colliding with 14 GeV positrons, a substantial step up from the energy of SPEAR. The Americans have similar plans but their new machine, called PEP, has also not been funded yet. If the United States does go ahead soon, PEP may be built a little more rapidly than EPIC since it can get its beams from the existing 20 GeV Stanford linear accelerator that now feeds SPEAR and other experimental facilities. But it takes a few years to do all the important experiments on a new accelerator, and there is plenty of room for two machines if they start work within a year or so of one another.

East African rift as membrane effect

from Peter J. Smith
Geomagnetism Correspondent

It is almost exactly a year since Turcotte and Oxburgh (*Nature*, **244**, 337; 1973) first sketched out their ideas on the nature of mid-plate tectonics. For some time before this (and even since), numerous workers had sought to explain the origin of major tectonic activity away from plate margins in the relatively *ad hoc* terms of hot spots, with or without mantle plumes. The Hawaiian-Emperor island chain, for example, was seen as the surface trace resulting from the motion of the Pacific plate over a stationary or near-stationary magma source—a not unreasonable explanation, although one difficult to substantiate in the face of older and equally plausible interpretations based on less contentious terrestrial phenomena. On the other hand interpretations of continental mid-plate tectonic features in terms of hot spots were much less successful. How, for example, could hot spots be held to account for the extension across graben and rift valleys?

In their original summary article, Turcotte and Oxburgh were able to abolish many such problems at a stroke, ironically by returning to explanations involving more traditional concepts. They argued that major mid-plate tectonic activity results from crustal extension due to tensional stresses. Clearly this is likely to offer a more satisfactory explanation for the finite extension of rift valleys, for extension would be required to relieve the stresses. In the case of the Hawaiian islands, it meant returning to the much older, though far from disproved, idea that the chain is a "propagating tensional fracture in the lithosphere which causes volcanic activity as it propagates".

But Turcotte and Oxburgh not only were to propose the mechanism (crustal extension), they were also able to suggest two plausible ways in which the required tensional stresses could be produced. The first type of stress, the theory of which was developed by Turcotte (*Geophys. J.*, **36**, 33; 1974), is the membrane stress arising from non-spherical plate tectonics. Because the Earth is not quite spherical, a lithospheric plate must deform as its latitude changes, producing regions of both compression and tension involving stresses of up to at least several kilobars. Second, there are thermal stresses, now discussed in greater detail by Turcotte (*J. geophys. Res.*, **79**, 257; 1974). As oceanic lithosphere moves away from the ridges, non-uniform cooling will lead to thermal stresses unless there is relief by plastic flow. In fact,

the upper lithosphere behaves elastically on geological time scales; Turcotte therefore concludes that thermal stresses up to 4 kbar (sufficiently large to fracture the lithosphere) may develop where the temperature is lower than about 300°C.

Presumably the forces giving rise to mid-plate tectonics generally arise from a complicated combination of membrane and thermal stresses, although the latter are clearly of particular relevance to the ocean floor. Indeed, in his most recent discussion in the *Journal of Geophysical Research*, Turcotte has suggested that even the transform faults and their associated fracture zones are contraction cracks which relieve the thermal stresses in the cooling lithosphere. In contrast to some other origins previously proposed for transform faults (for example, those involving small changes in spreading direction), thermal stress relief would explain the presence of such faults throughout the entire worldwide ridge system as well as in convecting lava pools (field) and freezing wax (laboratory). It would also explain why transform faults are apparently structurally similar to rift valleys. It would not explain directly why ridge segments are offset; but it is easy to envisage that once a thermal contraction crack appears in a ridge, small random variations in spreading rate on the two sides of the ridge will lead to offsetting.

Membrane stresses, on the other hand, are more obviously relevant to both ocean floors and continents; and it is to a plate comprising both continental and oceanic elements that Oxburgh and Turcotte (*Earth planet. Sci. Lett.*, **22**, 133; 1974) have now applied the concepts they have jointly and separately developed during the past year. The plate is the African plate; and the object of the exercise was to determine whether or not the formation and properties of the East African rift are explicable in terms of membrane tectonics.

The basic principle of membrane tectonics is that the two principal radii of curvature of a small plate at the Earth's surface will increase if the plate moves towards higher latitudes and, conversely, decrease if it moves towards lower latitudes. Thus an unstressed plate (regarded as a thin elastic shell) moving towards the poles will acquire a tension at the edge and a compression in the interior, whereas for a similar plate moving towards the equator the sites of tension and compression will be reversed. The difference between the Earth's polar and equatorial radii of curvature is such that a plate undergoing even a modest change in latitude (a few tens of degrees) will be subject to stresses comparable to the strength of the plate;

and so under the right circumstances large-scale lithospheric fractures may occur.

As interpreted by Oxburgh and Turcotte, the palaeomagnetic evidence suggests that, following a period of relative quiescence lasting most of the Mesozoic, the eastern part of Africa began to move northwards about 100 million years (Myr) ago at a rate of about 0.25° per million years. The western part of Africa, by contrast, began to move much more slowly. Taking into account the drift rate and the size of the African plate as extrapolated backwards throughout the past 100 Myr, Oxburgh and Turcotte calculate that the tensional stress in the centre of a circular plate the size of the African plate (and drifting towards the equator) would be about 135 bar, which seems to be of the same order as the stresses associated with current continental faulting. In other words, it is quite conceivable that the East African rift system was produced by membrane stresses in the lithosphere, developed in response to the rapid latitude change of eastern Africa during the late Cretaceous and early Tertiary—and that is precisely what Oxburgh and Turcotte propose happened.

It follows from this interpretation

that the East African rift system is probably a southward-propagating fracture system. There is little direct evidence on the age of the fracture itself; but it is implicit in a propagating fracture system that the onset of rift volcanism will migrate at the same rate as that at which the fracture extends. At most places along the East African rift, the volcanism, once started, has continued to the present; and so the onset of volcanism may be determined from the age of the oldest volcanic rocks available. Such age data from the eastern rift show that the locus of this onset has migrated southwards at a rate of about 0.23° per million years, which is in excellent agreement with the palaeomagnetically-determined northward drift rate of the eastern part of the plate. Numbers apart, however, the advantage of regarding the East African rift as a propagating fracture rather than the locus of a hot spot is that so much more can be explained. The tensional features of the rift are an obvious case in point. Equally, hot spots seem incapable of explaining why volcanism continues at any given point once the plate has passed over the spot; a propagating fracture, on the other hand, would imply continued dilation and thus continued volcanism.

The Oxburgh-Turcotte model is, of course, an oversimplification. The real African plate is not circular, does not remain the same size, and does not undergo a simple change of curvature. Moreover, the unstressed radii of curvature are not constant over the plate but vary from element to element within it. The oceanic lithosphere within the plate is subject to thermal stresses as well as membrane stresses; the location of fracturing within continental lithosphere may be governed partly by previous history of faulting; even mid-plate areas will be affected to some extent by interactions with neighbouring plates; and so on. But these are points of detail, rather than principle, which do not deflect Oxburgh and Turcotte from their view that membrane stress effects are substantially more plausible than hot spot processes.

Ribosome structure and function

from a Correspondent

THE EMBO meeting on ribosome structure (Göteborg, Sweden, June 27-30) was a field day for *Escherichia coli*. The most popular topic was the three-dimensional arrangement of the ribosomal proteins, where several different approaches are being used with considerable success. C. Cantor (Columbia University, New York) has used a fluorescence method in which reconstituted 30S ribosomes are labelled with two different fluorescent dyes on two specific proteins. By varying the proteins labelled, he has been able to classify many pairs of 30S proteins as being close, or far apart in the ribosome.

Experiments with bifunctional protein cross-linking reagents were reported by several delegates, the most impressive being those of R. Traut (University of California, Davis) who used the asymmetric reagent 4-mercapto-butyrimidate to establish nearly twenty pairs of cross-linkable proteins from both subparticles. This reagent reacts first with ϵ amino groups, leaving the thiol group free to react with protein sulphhydryl groups under oxidising conditions.

G. Stöffler and G. Tischendorf (Max-Planck-Institut, Berlin) have approached the topography question by electron microscopy. Since both subparticles have an asymmetric shape, it is possible to localise the positions of proteins by examining the complexes formed with the ribosome by individual protein-specific antibodies. So far twenty 50S and seven 30S proteins have been localised by this technique. H. Zeichhardt (Max-Planck-Institut, Berlin) used specific antibodies to examine the subparticle interface; although many

Internal magnetic field on Mercury?

from Peter J. Smith
Geomagnetism Correspondent

HITHERTO, it has not been considered likely that Mercury possesses an internal magnetic field. It is true that the planet has an unusually high density and thus by implication a large core; but the low rate of rotation would seem to preclude the generation of internal fields by dynamo action. Moreover, unlike Jupiter, Mercury has never produced any evidence of radio emissions which would indicate the presence of radiation belts.

The preliminary data from the Mariner 10 magnetic field survey near Mercury, now recorded by Ness *et al.* (*Science*, **185**, 151; 1974), are thus surprising. For on March 29, 1974 Mariner 10 passed within 704 km of Mercury's surface where it recorded a magnetic field of 98 γ , which is about five times higher than the average interplanetary field in the vicinity. Moreover, both a well developed bow shock wave and a magnetosphere-like region were observed — features comparable to those of the Earth, which has a global field, but completely alien to a body such as the Moon, which does not.

So do these results imply an in-

ternal Mercurian field? They certainly imply it, but do not prove it because there are other processes, such as field induction by solar wind interaction, which could just explain the limited data yet available. Another Mercury encounter will be required to settle the matter; but in the meantime Ness and his colleagues interpret the whole evidence as generally favouring the intrinsic field idea. Approximate figures then suggest that the Mercurian dipole moment is about 4×10^{-4} that of the Earth, that the dipole is close to the rotation axis and that it is offset by 0.47 Mercurian radii (not unacceptable in view of the large core).

A dynamo currently active within Mercury would indicate the viability of dynamo action under unexpected and unusual conditions. On the other hand, if the Mercurian field is due to remanent magnetism left from a dynamo now extinct, the implication must be that the planet once rotated much faster than it does now. In any event, internal planetary magnetic fields are rare enough to make the discovery of one within Mercury (if confirmed) a major advance in the exploration of the Solar System.

Fabs would inhibit the reassociation of subparticles, only one protein (L19) was inaccessible to antibodies in the 70S particle itself. H. Roth (Max-Planck-Institut, Berlin) has isolated more than twenty ribonucleoprotein fragments from LiCl cores of the 50S subparticle by digestion with nuclease. The fragments, separated on sucrose gradients, contained from two to twenty-eight proteins. With a few notable exceptions, the data from these various sources were in good agreement, and two topographical models of the 30S proteins were presented by R. Traut and A. Bollen (Université de Bruxelles).

On the RNA front, C. Ehresmann (Institut de Biologie Moléculaire, Strasbourg) reported the latest improvements on the primary sequence of 16S RNA, and C. Branlant (Institut de Biologie Moléculaire, Strasbourg) described some binding sites of 50S proteins on the 23S RNA, in particular the complex formed between 5S RNA (with L5, L18 and L25) and 23S RNA in the presence of L2. As far as primary structure of individual proteins is concerned, it seems that L7 and L12 have been strongly conserved during evolution; two acidic proteins from rat liver were shown to be related immunologically to L7/L12 (G. Stöffler and I. Wool, Max-Planck-Institut, Berlin), and the corresponding proteins from the halophile *Halobacterium cutirubrum* showed large homologous sequences (A. Matheson, National Research Council of Canada, Ottawa). S5 has again turned up as an altered protein in several ribosomal mutants, notably in revertants from valyl-tRNA synthetase mutants described by H. Wittman (Max-Planck-Institut, Berlin). K. Isono (Max-Planck-Institut, Berlin) also found alterations in the *Bacillus stearothermophilus* protein corresponding to S5 (as well as S12) in streptomycin-resistant mutants.

On the functional side, S12 was shown by A. Spirin (Academy of Sciences of the USSR, Poustchino) to exert a negative control over non-enzymatic translocation, since particles reconstituted without S12 showed increased activity in this assay. With the 50S particle, K. Nierhaus (Max-Planck-Institut, Berlin) found that L11 and L16 are the proteins responsible for chloramphenicol binding. L6 is also important for the chloramphenicol effect, but does not actually bind the antibiotic. L11 binds thiostrepton (J. Gordon and J. Highland, Friedrich Miescher Institut, Basel), and is also involved together with L18 at the peptidyl transferase centre, as was shown by C. Cantor with a peptidyl tRNA photo-affinity label. E. Küchler (University of Vienna) also used a photo-affinity label to demonstrate that peptidyl tRNA can be

bound to 23S RNA near to the binding site of the 5S RNA-protein complex. Evidence for conformational changes during protein synthesis came from D. Vasquez (Instituto de Biología Celular, Madrid), who found that the antibiotic anisomycin binds to eukaryotic ribosomes with different affinities according to the functional state of the particles.

Looking at the more intimate details of tRNA binding, M. Sprinzl (Max-Planck-Institut, Göttingen) used suitably modified tRNA analogues to demonstrate that tRNA synthetases attach the amino acids to the 2'-hydroxyl position of the terminal ribose. Elongation factor T_u also recognises only a 2'-acylated tRNA. Peptidyl transfer can be effected to either a 2'- or 3'-acylated tRNA at the A site, but only from a 3'-acylated moiety at the P site. V. Erdmann (Max-Planck-Institut, Berlin) showed that the oligonucleotide T ψ CG can be used instead of a complete de-acylated tRNA to stimulate magic spot synthesis.

Last but by no means least, M. Nomura (University of Wisconsin, Madison) reported some elegant experiments with λ phages containing various amounts of the genetic material in the *aroEstrA* region of the *E. coli* genome. Using a DNA-dependent protein-synthesising system, he found that at least ten 30S and fourteen 50S proteins are encoded within this segment of DNA. The technique offers the possibility of detailed mapping of the ribosomal protein genes.

How microorganisms damage plants

from a Correspondent

In plant, as in animal pathology much research effort has been directed towards investigating the mechanisms by which pathogens damage their hosts. One of the most important advances of recent years has been the realisation that in a small, although by no means unimportant group of plant pathogens, the ability to produce toxin is the major factor determining virulence towards specific hosts. The most convincing experiment to demonstrate this relationship was performed by Scheffer and his associates (*Phytopathology*, **57**, 1288; 1967). They crossed two closely related toxin-producing fungi *Cochliobolus victoriae* and *C. carbonum*, pathogens, respectively of oats and maize. F₁ offspring segregated in a 1:1:1:1 ratio for the abilities to produce *C. victoriae* toxin, *C. carbonum* toxin, both toxins or no toxin. These progeny were, respectively pathogenic on oats, maize, both oats and maize or neither host.

Attempts to elucidate the mechanism

of action of these host-specific toxins have been stimulated by the knowledge that these toxins comprise some of the most potent biologically active substances known. Root growth of susceptible oat seedlings treated with *C. victoriae* toxin is prevented by as little as 0.0002 μ g toxin ml⁻¹, a potency approaching that of the more active clostridial toxins. In susceptible plants almost any metabolic system that one chooses to examine is deranged by toxin treatment. Many of these changes are undoubtedly secondary effects and evidence is accumulating that the primary site of action of at least some toxins resides in the plasmalemma. Supporting evidence for this hypothesis comes from the findings that toxin treatment of susceptible host cells leads to a rapid leakage of intracellular contents (Scheffer and Samaddar, *Rec. Adv. Phytochem.*, **3**, 123; 1970; Keck and Hodges, *Phytopathology*, **63**, 226; 1973), to a rapid depolarisation of the plasmamembrane potential (Novacky and Hanchey, *Physiol. Pl. Path.*, **4**, 161; 1974) and also results in an inhibition of solute uptake and failure of the protoplasts to plasmolyse in hypertonic solutions.

Even more convincing evidence has come from the studies of Strobel and his associates (*J. biol. Chem.*, **248**, 1321; 1973; *Proc. natn. Acad. Sci., U.S.A.*, **70**, 1693; 1973; *ibid.*, **71**, 1413; 1974) on the eyespot disease of sugar cane caused by *Helminthosporium sacchari*. The toxin produced by this fungus seems to be a primary determinant of disease and has been characterised as 2-hydroxy-cyclopropyl- α -D-galactopyranoside. Strobel has found that sensitivity to the toxin is correlated with the presence of a specific toxin-binding receptor protein in the plasmalemma of susceptible cells. Those cells resistant to the toxin possess an immunologically identical protein which does not bind the toxin. The specific proteins from resistant and susceptible cells have similar molecular weights, both consist of four subunits but differ slightly in electrophoretic mobility and with respect to four different amino acid residues.

This is the first positive identification of a specific chemical factor associated with disease susceptibility in a higher plant, an association long suspected on theoretical and genetical grounds. Although these reports establish the presence of a toxin-binding protein within the plasmalemma, much remains to be discovered as to the mechanism by which the toxin-protein interaction destroys the normal functioning of the membrane. These reports also illustrate another basic similarity between the functioning of animal and plant cells and suggest that the study of plant cell surfaces should prove useful.

The ageing, growth and death of cells

A. R. Sheldrake

Department of Biochemistry, University of Cambridge, Cambridge, UK*

The ageing and death of cells in higher plants and higher animals is discussed in relation to cellular rejuvenation by growth and division.

No cell is immortal. If a cell grows and divides, it becomes two cells; if it does not divide, sooner or later it dies. Multicellular organisms are not aggregates of cells in a state of exponential growth and division. Some cells divide, but most differentiate and do not undergo further division. Here I shall discuss the ageing and death of cells in vascular plants and vertebrate animals in an attempt to explore the significance of these processes in relation to growth and development, both normal and abnormal.

It is often convenient to think of cells or living organisms as maintaining a more or less steady state; but it is also easy to forget that this is an approximation, an abstraction which, if realised, would confer on cells and on organisms the doubtful blessings of eternal life and eternal youth. The realities of growth, development, ageing and death cannot be understood in terms of steady state concepts. They are directional and irreversible changes in time.

Some cells die as they differentiate, for example xylem cells in plants and keratinised epidermal cells in animals; some, such as phloem sieve tubes in plants and red blood cells in mammals, lose their nuclei; others which retain their nuclei may lose their ability to divide—as do most nerve cells. But even cells which retain their ability to divide will die if they do not do so; they senesce.

Any general hypothesis of cellular ageing must not only explain cellular ageing itself, but also the way in which some cell lines do not senesce and die out. The germ cell line is continuous from generation to generation (also many plants can be propagated vegetatively indefinitely) and some cell lines derived from plant or animal tissues can be propagated *in vitro* for an indefinite number of generations.

General hypotheses of ageing based on genetic mutation face two difficulties. First, in explaining the universality of the processes of ageing in non dividing cells in terms of a lethal accumulation of harmful mutations and, second, in accounting for the facts of sexual and vegetative reproduction, which show that mutations do not accumulate to a lethal extent in all cells. The alternative to a genetic-mutation hypothesis of ageing is some sort of 'cytoplasmic' hypothesis, the most recent and best known of which is Orgel's 'error catastrophe' hypothesis, which postulates that an accumulation of errors in protein synthesis leads to a positive feedback of error as the enzymes involved in protein synthesis themselves develop errors and thus produce more defective proteins¹. For this hypothesis to account for the continuity of the germ line and the indefinite propagation of 'permanent cell lines' *in vitro* it is necessary to postulate a process of 'cellular selection' whereby error-containing cells are selected out².

Neither the genetic-mutation hypothesis³ nor the protein synthesis 'error catastrophe' hypothesis² of ageing are supported by sufficient evidence to rule out the possibility that cellular ageing may be explicable in terms of the accumu-

lation of cytoplasmic breakdown products, some of which might be deleterious to the cell if they accumulated sufficiently. In all actively metabolising cells, there is a turnover of cytoplasmic constituents such as proteins and membrane lipids. More is known about their synthesis than about their breakdown *in vivo*; while some of them may be broken down completely, others may be broken down only partially or not at all. They must therefore accumulate.

Lipid peroxidation

One example of such an accumulation is provided by the 'age pigment' or lipofuscin granules which accumulate in an age-dependent way in the cells of many mammalian tissues⁴. The lipofuscin material contains lipid and protein and may be formed in autophagosomal vesicles, for example during the digestion of mitochondria; haem groups, released as the cytochromes are degraded, may catalyse the peroxidation of unsaturated lipids in the degenerating mitochondrial membranes⁵ which may cross link with each other and with denatured proteins⁶. The cells seem to be unable to destroy these cross-linked polymers. Lipofuscin granules do not seem to damage cells directly except when they accumulate, as they do in certain diseases, to such an extent that they mechanically interfere with the structure and functions of the cell⁷.

Lipid peroxidation does not always result in the formation of microscopically visible lipofuscin granules, nor is it confined to autophagosomal vesicles; it occurs in all functional cell membranes, including the surface membrane. Once the peroxidation of unsaturated lipids is initiated, by haem groups, Fe²⁺ ions and other simple catalysts in the presence of oxygen, it takes place by a free radical chain reaction. It can be inhibited by lipid-soluble antioxidants such as vitamin E and accelerated by vitamin E deficiency, ionising radiation, chloroform and ethanol poisoning and hyperbaric treatments^{8,9}, which can cause irreversible damage to cells.

The peroxidation of lipids within cell membranes is occurring *in vivo* all the time. Some peroxidised lipids may be metabolised⁹ but others, perhaps those which are cross linked to other lipids and lipoproteins may not be. The chain reaction of lipid peroxidation may be terminated by the oxidation of other substances which may themselves be damaged and accumulate¹⁰. Such substances formed within the surface membrane, for example, may accumulate *in situ*; if they are removed from the surface membrane as the membrane is recycled by the invagination of membrane vesicles¹¹⁻¹⁴ or by other means, some of them might find their way into residual bodies, but they might also be incorporated into intracellular membranes. The formation and accumulation of such substances within the outer and intracellular membranes, for example in the Golgi apparatus, endoplasmic reticulum nuclear membrane and lysosomal membranes, could well be deleterious to normal membrane functioning and could also lead to a positive feedback of damage by further lipid peroxidation, and thus to the senescence and death of the cell. The rate of ageing would be temperature dependent and would also depend on the composition, structure and functions of the cellular membranes, the extra- and intracellular environments, antioxidant levels and so on. Thus, different types of cells would

* Present address: International Crops Research Institute for the Semi-Arid Tropics, 1-11-256, Begumpet, Hyderabad 500016, A.P., India.

age at different rates but, according to this hypothesis, all cells would be ageing to a greater or lesser extent all the time; all cells would be heading towards senescence and death.

The elimination of membranous material from cells might enable the ageing process to be retarded and there are a few examples of the shedding of membranes by cells which I will discuss further. But, in general, the only way in which cells could avoid their otherwise inevitable mortality would be by growing and dividing, thus diluting the accumulated breakdown products. Although lipid peroxidation may be the most important cause of the formation of such substances, the following general considerations could apply to any deleterious substances which accumulate with age.

Growth and division of cells

An artificially simple case is provided by cells dividing symmetrically with a fixed generation time if these accumulate deleterious breakdown products linearly with time, an amount, x , being formed per cell generation time (Fig. 1). Successive generations contain more of the accumulated breakdown products but the increments become smaller and smaller. If the rate of accumulation is not linear, but proportional to the amount already accumulated, the content per cell will increase exponentially; and if there is a progressive lengthening of the cell generation time, there will be a greater accumulation within individual cells in succeeding generations. With either or both of these assumptions, it can be seen that the whole population will undergo senescence and sooner or later die out.

But another type of cell division is possible, an asymmetrical division in which one of the daughter cells receives all or most of the accumulated breakdown products (becoming more 'mortal') while the other is rejuvenated, receiving little or none. The more 'mortal' of the daughter cells might die or differentiate directly, or it might divide again unequally, producing a rejuvenated cell and a cell even more 'mortal' than itself, or it might undergo one or more sequential symmetrical divisions (as discussed above) to produce a population of cells which sooner or later die (unless they can undergo further asymmetrical divisions to produce rejuvenated cells).

Fig. 1 Cells dividing symmetrically with a fixed generation time showing the accumulation of deleterious breakdown products linearly with time, an amount, x , being formed per cell generation time.

I shall now consider a few aspects of the growth and development of higher plants and higher animals in the light of these ideas. Dicotyledonous trees illustrate the pattern of indefinite growth that is characteristic of plants. (There are of course plants, such as herbaceous annuals, which die after they have flowered. But annuals are capable of growing for much longer than their normal life-span if they are prevented from flowering, indicating that they die because they flower and not because of an innate inability to go on growing¹⁵.) The life span of trees is limited by a variety of mechanical factors, but cuttings taken from old trees can give rise to healthy young trees, and this process can be repeated indefinitely. The growing points of the tree, the apical meristems, remain perpetually young.

Cell divisions within the apical meristems of the shoots give rise to daughter cells with different fates: some remain meristematic, others give rise to the differentiated structures of the stems and the leaves. Some of these cells die as they differentiate into vascular tissues and fibres, others, for example the leaf mesophyll and pith parenchyma, remain alive for some time, but, unless they are stimulated to divide again in a regenerative response to wounding or damage, they eventually die. The leaves senesce and fall from the tree; the pith breaks down. The root meristems give rise to the primary tissues of the root which, apart from those which divide to produce further root meristems, sooner or later die. In secondarily thickening stems the divisions of the cambial cells give rise to cells which die as they differentiate into xylem or undergo further asymmetrical divisions to produce phloem companion cells and sieve tubes. These cells eventually die and are sloughed off in the bark. Cell divisions in the cork cambium give rise to cork cells which die as they differentiate; divisions of the root cap initials give rise to root cap cells which die and are sloughed off. Thus, in the various meristems of the plant the continued growth and continued rejuvenation of the meristems is associated with the production of cells which die during or after differentiation.

Vertebrates

Vertebrates, unlike trees, do not go on growing indefinitely, nor can they be propagated vegetatively. At first, fertilised eggs undergo cleavages which rapidly increase the number of cells, but this rate of increase of cell number declines progressively as the animal develops, and as cells and tissues differentiate¹⁶. Throughout the development of the embryo many tissues and groups of cells regress and die^{17,18}. Some of these cell deaths are associated with tissue differentiation¹⁹, some occur during morphogenetic processes²⁰, and others may represent the regression of phylogenetically vestigial structures¹⁷, but the significance of other cell deaths is obscure¹⁷. As the animal develops, the cells of some tissues, such as nerve and muscle, differentiate and to a large extent lose the ability to undergo further division. Some of these cells die as the animal grows older and are not replaced^{21,22} but in the adult animal a number of other tissues continue to grow, for example the epidermis, the intestinal lining, the liver and blood cells continue to be formed. In all these examples the production of new cells is offset by cell death. Cell divisions in the basal layers of the mammalian epidermis give rise to daughter cells which remain in the basal layers and divide again, and other daughter cells which differentiate and keratinise, dying as they do so. Cell divisions in the crypts of the intestinal villi replenish the population of crypt cells capable of further division and produce other daughter cells which move up the villi where they die and are sloughed off²³. Asymmetrical divisions of the early precursors of all cells of the blood occur throughout life and give rise to further precursor cells as well as to the maturing and mature cells of the blood, all of which have a limited life span. During

the formation of red blood cells²¹ and granulocytes²⁵ in the bone marrow, and lymphocytes in the thymus²⁶, considerable numbers of cells die *in situ* soon after they are formed. The reasons for this 'ineffective' erythropoiesis, granulopoiesis and lymphopoiesis are unknown.

The mortality of at least some of the cells which die in developing animal embryos and in mature animals may represent the price that is paid for the rejuvenation of other cells which continue to grow and divide. But unfortunately too little is known about cell lineages in animals, especially in embryos, for it to be possible to decide how general is the phenomenon of asymmetrical cell divisions giving rise to daughter cells of unequal mortality. The recognition of this pattern is complicated by the fact that by no means all cell death takes place as a result of cellular senescence. Some cells die as they differentiate and others may die because they find themselves in the wrong places at the wrong times¹⁹. Cell deaths may be controlled chemically, for example by steroid hormones: the injection of glucocorticoids can cause large numbers of lymphocytes to die²⁷, the regression of Mullerian and Wolffian ducts is controlled by androgens and oestrogens^{19,28} and the regression of the lining of the female genital tract is under the control of oestrogens²⁸. But, under the hypothesis that asymmetrical cell divisions lead to a rejuvenation of 'meristematic' daughter cells at the price of the increased mortality of their sister cells, it does not matter whether the latter die as a result of senescence, or whether they die as they differentiate or for any other reason.

Sexual reproduction

In the sexual reproduction of both higher plants and higher animals almost all the cytoplasm from which the embryo and the new organism develops is provided by the egg. In both cases, the egg cells are formed as a result of asymmetrical divisions of the egg mother cell. In the great majority of higher plants, the meiotic divisions of the egg mother cell produce four cells, three of which die. The fourth undergoes further divisions to produce the cells of the embryo sac, most of which die before or shortly after fertilisation. In some species, one or more of the three sister cells of the cell which gives rise to the egg may undergo further division to produce short-lived embryo sac cells²⁹. In animals the first and second meiotic divisions of the egg mother cell give rise to the first and second polar bodies, which regress and die^{30,31}.

It is particularly striking that in both plants and animals, only one of the progeny of the egg mother cell gives rise to an egg while the sister cells die (or if they divide give rise to short-lived progeny). By contrast, there is no comparable cell loss in male gametogenesis associated with the meiotic divisions of the pollen mother cells and spermatogonia.

The many examples in both higher plants and higher animals (and many more can be found in the lower plants and lower animals) of the production of rejuvenated meristematic, stem or egg cells by asymmetrical divisions do not of course prove that these divisions involve an asymmetrical distribution of deleterious breakdown products; but the available facts appear to be consistent with this hypothesis.

Loss of membranous material by animal cells

If the accumulation of deleterious breakdown products of membrane lipids is one of the causes of cellular senescence, the loss of membranous material might be of considerable importance in enabling cells to rid themselves of such substances. The shedding of membranous material by living cells does not seem to be of common occurrence but can take place in mammalian cells as follows.

First, in apocrine secretions part of the cell membrane is

lost. The best example, and the only one for which conclusive ultrastructural evidence exists, is in the secretion of lipid droplets by the cells of lactating mammary glands. The secreted lipid droplets are surrounded by a unit membrane derived in part from the surface membrane and in part from Golgi vesicle membranes³².

Second, membrane-bounded vesicles of cytoplasm can break away from mammalian macrophages both *in vitro* and *in vivo*³³. This process, known as clasmotosis, is of unknown significance. Lymphocytes which are activated in immunological reactions or as a result of phytohaemagglutinin stimulation form 'tails' (uropods) which can bleb off vesiculated buds *in vivo* and *in vitro*³⁴. Again, the significance of this process is unknown. Clasmotosis is also frequently observed in cultures of fibroblasts.

Third, many types of animal viruses are budded off from host cells in membrane-bounded vesicles. The protein in the membrane of the vesicles is largely viral, at least in the case of RNA tumour viruses, but the lipids are derived from the host cell membrane³⁵. Viral particles bounded by membrane are also budded off from the cells of a number of spontaneously cancerous tissues³⁶ and from many of the cell strains and permanent cell lines which are commonly cultured in laboratories³⁷.

Tissue cultures

Many plant callus cultures can be grown indefinitely *in vitro*. During the early stages of the growth of some calluses, an exponential increase in cell number takes place at a rate which suggests that many of the cells may undergo a limited number of sequential symmetrical divisions before the growth rate declines^{38,39} but in most plant tissue cultures the rate of increase of cell number is more or less linear for most of the growth period^{39,40}. Linear growth characteristics would be compatible with a meristematic pattern of cell division such that some daughter cells continue to grow and divide while their sister cells age and sooner or later die. Unfortunately nothing is known in detail about cell lineages within these cultures, nor are there any quantitative data on cell death. Nevertheless, dead and dying cells are by no means uncommon.

'Permanent' mammalian cell lines capable of indefinite propagation *in vitro* can be derived from cancerous tissues and also from cells which have undergone a spontaneous 'transformation' during culture. Diploid fibroblast cultures can be propagated, however, only for a finite number of subculturings, more (up to about 60) if the cells are derived from embryonic tissues, fewer if they are derived from mature organisms⁴¹. The number of generations through which the cells can be passed before the population senesces and dies out is reduced if the period of time between the subculturings is increased⁴². Fibroblasts of the mouse L strain have been observed to divide symmetrically over six to seven cell generations with a more or less constant generation time⁴³; if the cells in the diploid fibroblast cultures also divide symmetrically, deleterious breakdown products might accumulate in the cells of succeeding generations, as discussed above, and account for the senescence of these cultures. It is impossible, however, to make any detailed interpretation of the senescence of these cultures in the absence of quantitative information about the proportions of dividing and nondividing cells, the incidence of cell death, and the extent and significance of clasmotosis within these cultures—or indeed with cultures of 'transformed' and 'permanent' cell lines.

Cancer

Malignancy must not only involve the freeing of cells from the normal controls on their proliferation, but also the avoidance of senescence by at least a part of the cell population. Many animal tumours contain a stem cell or

'meristematic' population which gives rise to daughter cells which may or may not differentiate, but which sooner or later die⁴⁴. There are numerous examples of cell death within cancerous tissues⁴⁵⁻⁴⁸. Some of the cell deaths can be explained in terms of an inadequate vascularisation of the tumour tissue, but in most tumours this is by no means the only cause and does not apply at all to leukaemias; many of the cells may die as a result of ageing⁴⁴.

Little attention has been paid to the incidence of cell death within cultures of cancerous cells and it is therefore at present impossible to know to what extent the patterns of cell division, ageing and death within these cultures resemble those within *in vivo* cancers. It is sometimes assumed, if only implicitly, that overall exponential growth characteristics of cell cultures mean that there is a homogeneous population of symmetrically dividing cells. This assumption is not justified: a heterogeneous population containing proliferating, nonproliferating and dying cells can also grow exponentially if the proportion of cells that die is constant with time^{49,50}.

It is conceivable that the loss of membranous material either spontaneously, as in certain types of mammary gland tumours⁵¹, or as a result of the budding off of viruses (such as RNA tumour viruses) could play a significant role in the retardation of cellular senescence in certain types of cancer.

Effects of cell death

Very little is known about the biochemistry of dying cells. Such cells probably release all sorts of proteins, glycoproteins, peptides, amino acids, amino acid breakdown products, nucleic acids and nucleic acid breakdown products, lipids and lipid breakdown products as well as salts and other substances which were sequestered inside the cells.

It has recently been found that in higher plants the hormone auxin (indole-3-acetic acid) is formed as a consequence of cell death as tryptophan, released by proteolysis, is broken down. Dying cells in differentiating vascular tissue, regressing nutritive tissues and so on, are probably the major source of this hormone within the plant⁵². Other plant hormones may also be produced by damaged and dying cells: ethylene from the breakdown of methionine and cytokinins by the hydrolysis of transfer RNA⁵². In higher plants the normal production of hormones as a consequence of cell death and the production of 'wound hormones' by damaged cells can be seen as two aspects of the same phenomenon⁵².

Wound and regenerative responses in vertebrates cannot be explained simply in terms of wound hormones, but there is evidence that dying cells release substances that stimulate phagocytosis⁵³, and affect growth and development in both normal^{54,55} and cancerous tissues⁵⁶. And at least some of the cell deaths which occur during normal embryonic development may well result in the production or release of substances involved in the control of differentiation and development.

Dying cells may not only have a chemical effect on neighbouring cells but also a physical effect as cell to cell contacts are broken. Cell deaths within a tissue may also affect the functioning of the tissue as a whole: for example, the death of nerve cells within the brain²² seems likely to affect pathways or patterns of nervous conduction, perhaps leading to the formation of new pathways or patterns. Such cell deaths could act as a source of random change within the nervous system that might not always be deleterious⁵⁷.

So little attention has been paid to the ageing and death of cells during growth and development, both normal and abnormal, that detailed information about these processes is scarce. Where facts are few, speculation can flourish. Most of the speculations advanced in this article could be

opposed by alternative speculations, but they illustrate the view that growth and development cannot be understood in isolation from ageing and death. This is by no means an original concept, but at the cellular level it provides a perspective in which many familiar facts take on a new significance and suggests a new approach to familiar problems.

I am indebted to Dr A. Glücksmann, Dr W. Jacobson and Professor E. N. Willmer for helpful comments, criticism and discussion.

Mount Etna erupted for the first time in 31 months on January 30, 1974. The eruption, which continued until February 16, was watched closely between January 30 and February 15 by Italian and British members of the Etna Research Programme. This article summarises their observations.

On January 30, 1974 Mount Etna erupted for the first time since the middle of 1971 (ref. 1). Between these eruptions, activity on the volcano had been restricted to strombolian explosions and the extrusion of lava at the bottom of two deep pits within the summit crater. The centre of the new eruption lay 5.75 km to the west of the summit crater, at an altitude of about 1,680 m (grid ref. 938776 on the Monte Minardo 1:25,000 map sheet).

The eruption was first noticed at about dusk on January 30, but it probably started during the afternoon. The first observed activity was the occurrence of strong, almost continuous (30-50 a minute), strombolian explosions which threw bombs to a maximum of 700 m, and rapidly built up a cone. The first erupted lavas (Flow 1) were observed on January 31, as 2-3 m thick aa flows (Fig. 1). At this time the flow front was at the foot of Mt Nuovo (which erupted in 1763). During the next four days, two more lava streams (Flows 2 and 3) were emitted, forming parallel flows which extended between the new cone and that of Mt Nuovo. After three (?) days the explosive activity had decreased in rate to about 25 explosions a minute.

On February 2 (?), two short, thick, viscous flows (Flows 4) erupted from boccas on the eastern side of the cone. They were more than 20 m thick and short lived, and later became largely covered by ash from the cone. Another viscous lava, observed on February 6, probably started erupting on the previous day from a bocca on the northern side of the cone. This flow (Flow 5), an aa flow with a maximum thickness of about 10 m at its front, was advancing on a 70-80 metre front, at a maximum flow rate of 1 m h⁻¹. This rate was, however, evidently reduced, implying that earlier rates must have been much higher to give rise to this flow. The flow stopped on February 7, by which time there was no flowing lava, although the explosion

rate in the crater continued at about 14-16 explosions a minute, with maximum projectile heights of about 500 m. On February 8, strong blizzards prevented any observation but by February 9 the violent strombolian activity had changed to occasional explosions which ejected bombs to about 100 m above the crater lip, and there were rumblings within the crater. We considered the magma level in the cone to be very low at this time. On the same day a new aa flow about 800 m long (Flow 7) was discovered emanating from a bocca at the foot of the cone on the south-eastern side of the volcano. The bocca was in a hollow 120 m across with a flat floor containing a small lake of

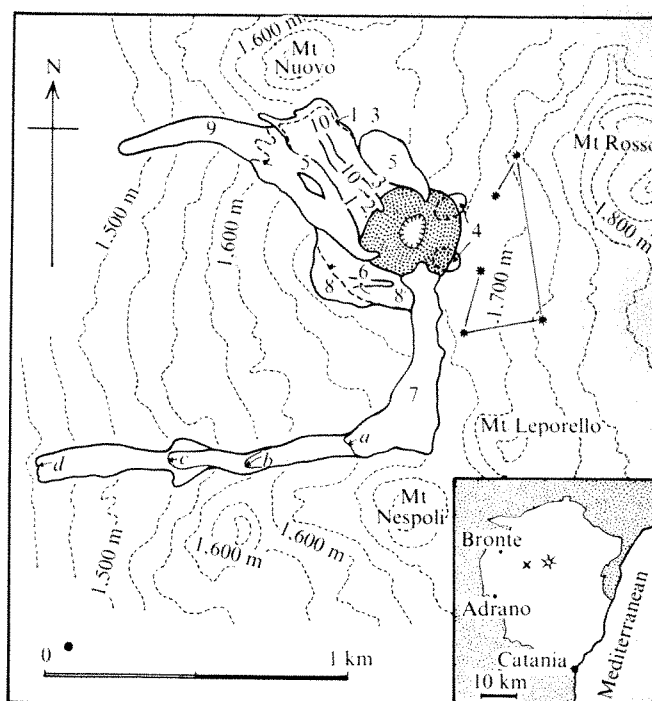

Fig. 1 The area around the eruption site of Mt Etna, Sicily, showing the course of the eruption of January 30 to February 16, 1974. 1-10, Flow numbers (see text); a, the extent of Flow 7 on February 9; b, February 10; c, February 11; d, February 15; *, e.d.m. station. Inset: x, January 1974 eruption, *, summit of Mt Etna.

viscous lava. Lava from this lake was pouring down a short 40° slope towards Mt Leporello, where it turned westwards. The active flow front was about 80 m across and was moving slowly, except on a slope of about 9° down a dirt track, where a flow 3 m across and 1.5 m high advanced at a rate of about 33 cm min⁻¹. The rate of eruption at the bocca was variable and apparently stopped late on February 9, only to restart a few hours later, early the following morning. An examination on February 9 had shown that before this flow, an earlier flow (Flow 6) from the same bocca had flowed around the side of the cone and towards Mt Nuovo, probably on February 8. This flow was about 2–5 m thick.

On February 10, the explosive activity was still discontinuous, with occasional periods of stronger activity (12 explosions every minute) throwing bombs about 150 m above the lip of the cone. The extrusion of lava was also irregular and late in the day the flow front was hardly moving, although several new lobes had developed along the southern side. By the morning of February 11, the lava had moved another 250 m and there were only occasional explosions in the crater. Most of the ejected material was derived from collapses of the crater walls. A gas jet formed at the bocca of Flow 7 and sublimates were deposited. The flow front was advancing at about 30 cm min⁻¹, but it had slowed down to 1 m h⁻¹ on an 80-m front by February 13. On that day it was discovered that a bocca had opened on the south side of the cone. Lava (Flow 8) from this bocca was flowing around the foot of the cone, towards the west. By 1700h LT, Flow 7 had stopped and Flow 8 was flowing at a rate of 0.3 m min⁻¹. A new bocca (1–2 m across) had opened to the west of the cone, extruding lava (Flow 9) which flowed at a rate of 3 m min⁻¹. Another bocca (Flow 10) to the north-north-west of the cone had also apparently opened but we did not visit this until the next day. Weak explosions continued in the crater, and there were strong rumblings with gas explosions which ejected a little pyroclastic material. Ground shocks could be felt up to 900 m from the cone. By February 14, Flow 8 had stopped, but Flow 9 was still erupting, flowing at about 2.5 m min⁻¹ in a flow 3–5 m wide. On February 14 and 15, the inner walls of the cone suffered major collapses. On the latter day, we observed radial fractures on the southern and western flanks of the cone. The rate of flow in Flow 9 was about 4 m min⁻¹ and Flow 10 was erupting at a rate of 2 m min⁻¹ and was 1.5 m wide. By February 17, the activity had stopped. Twenty-three days later a further period of activity began in the same area, about 200 m to the south-west of the centre of activity which we had been observing.

We computed the amounts of lava which were erupted during the February period of activity: between January 30 and February 7, 1.0×10^6 m³; February 8 and 9, 1.0×10^6 m³; February 10–15, 0.35×10^6 m³. This is a total of 2.35×10^6 m³, giving an average rate of eruption of about 1.5 m³ s⁻¹, although on February 8 and 9 the rate may have been more than 6 m³ s⁻¹ for a short period, thus lowering the level of magma in the cone and reducing the strength of the explosions.

Viscosities inferred from the rate of flow in channels of Flow 6 were about 1.8×10^3 poise 50 m downstream from the bocca, where lava surface temperatures were about 980° C (measured with an optical pyrometer), and about 1.0×10^6 poise near the flow front, where lava surface temperatures of 962° C were measured (using an optical pyrometer and a thermocouple). In the boccas of Flow 6 and later flows, maximum temperatures of 1,060° C were measured with a thermocouple inserted to 20 cm.

Activity at the central crater

We visited the Central Crater at the summit of Etna (3,200 m) on February 12. There are two pits within the summit

Table 1 Analyses of lavas and bombs*

† Fresh bomb ejected on February 7, and partially quenched in snow.

‡ Quenched lava from the front of Flow 7 (February 11).

crater², but only one, the Bocca Nuova, showed any significant activity—the spasmodic expulsion of clouds of very fine, brown ash, accompanied by muffled explosions, which were estimated to originate from a depth of several hundred metres. Quiet emission of fume was occurring at both the Chasm and the 1964 Crater, but the NE Crater remained inactive.

The vigorous strombolian activity which characterised the Chasm and the Bocca Nuova during parts of 1973 left a deposit of ash and bombs near the Chasm. This activity, which reached its culmination in November, seems to have raised the floor of the Chasm from about 150 m to about 75 m below its lowest lip. Since then, however, there has been a lowering of the Chasm floor. It now falls in a series of steps produced by arcuate fractures, towards a deep, central pit, 50 m across, from which most of the gas emerges.

This seems to indicate that there has been a drop in magma level or pressure on the Chasm–Bocca Nuova conduit system, possibly connected with a movement of magma away from there, and into the western side of the volcano.

Electromagnetic distance measurements (e.d.m.), on the southern side of the volcano, at a height of 2,000 m, indicate a significant amount of deflation of the volcano since July 1973. A quantitative assessment of the role played by the central magma conduit system during the eruption described here must, however, wait till the summit e.d.m. network can be measured later in 1974.

A small e.d.m. network was set up on the eastern side of the eruptive site (Fig. 1) and repeatedly measured from February 10 to February 15. There were no movements recorded above the level of error of the measurements, (± 8 mm, Hewlett-Packard 3800 B).

Eruption type

Compared with known Etnaean eruptions, this eruption had lower rates of effusion, a high viscosity, greater explosivity, possibly lower temperatures and a higher crystallinity of the lavas on extrusion. Ancient eruptive cones with small lava flows nearby suggest that, locally, this type of activity has been common.

Rittmann³ has classified types of eruption on Etna to include: lateral eruptions, which occur because magma migrates from the central conduit below the summit crater to fissures on the lower flanks; and eccentric eruptions, supplied independently of the central magma conduit. The differences between the eruption described here and the clearly lateral eruptions (for example, the 1971 eruption),

considered together with the seismic activity and the differences in petrology between the new lavas and those present in the Central Crater a few months before the eruption, suggest that this new eruption is fed by a conduit that is not related to the central conduit (eccentric eruption). On the other hand, Guest¹ noted a rise in fumarole temperatures on the western side of the summit crater in 1972 (and in 1973), and predicted a westward migration of magma from the central conduit. Furthermore, the summit pits were active up to a few days before the latest eruption, but they became inactive after the new outbreak, except for deep explosions in the Bocca Nuova. This would be expected for a lateral eruption, although it does not necessarily preclude an eccentric eruption. Unfortunately, heavy snow and bad weather conditions prevented distance measuring at the summit.

Further work on the petrology and chemistry (Table 1) of the lavas, together with geodetic studies, will help to determine the origin of the eruption.

Drs R. Romano and L. Villari of the Instituto Internazionale di Vulcanologia, Catania made available their observations and provided help in the field.

Guest, Huntingdon and Wadge acknowledge financial assistance from the Royal Society for travel and subsistence. Dr M. K. Wells drafted Fig. 1 from a compilation of field observations.

Androgen transport and receptor mechanisms in testis and epididymis

To influence spermatogenesis and sperm maturation, androgen has to be transported from the Leydig cells to the germinal epithelium and epididymis. This article describes extracellular transport and intracellular receptor mechanisms for androgen.

SPERMATOGENESIS is an androgen dependent process which can be maintained in hypophysectomised rats by the administration of either testosterone¹ or 5 α -dihydrotestosterone². Gonadotrophins may exert their effects on spermatogenesis indirectly by way of androgens. The sole action of luteinising hormone (LH) seems to result from the stimulation of testosterone synthesis by the interstitial Leydig cells. Follicle stimulating hormone (FSH) is necessary for the full maintenance of spermatogenesis, but its effects can be mimicked by androgens and blocked by the 'anti-androgen', cyproterone, indicating that its action is serially linked with androgen¹ or that androgen is the mediator of FSH action.

Androgen binding protein

An androgen binding protein (ABP) with high affinity for 5 α -dihydrotestosterone (DHT) ($K_a = 1.25 \times 10^9 \text{ M}^{-1}$) and testosterone ($K_a = 0.5 \times 10^9 \text{ M}^{-1}$) has been demonstrated in 105,000g supernatants of rat testis and epididymis³⁻¹⁰. ABP is produced in the testis, secreted into testicular fluid and carried to the epididymis by the efferent ducts^{9,10}. The concentration of ABP in efferent duct fluid (EDF) ($4-8 \times 10^{-8} \text{ M}$) is sufficient to bind testosterone and (or) DHT in a concentration of 13-26 ng ml⁻¹, assuming one binding site per molecule ABP (ref. 10). Ligation of efferent ducts

causes ABP to disappear completely from caput epididymidis supernatant within 3 d, suggesting that the testis is the only source of ABP in the epididymis⁹. ABP must be produced within the seminiferous tubules, since it is present in EDF and is absent from testicular lymph; also, the presence of ABP in testis supernatants following complete destruction of the germ cells by X-radiation or chemicals, like nitrofurazon, suggests that ABP is formed by Sertoli cells (Hagenäs *et al.*, unpublished observations). It seems that ABP might have an important function in the transport of testicular androgen to the germinal epithelium as well as to androgen-dependent epithelial cells in the epididymis.

ABP in efferent duct fluid and supernatants of testis and epididymis

Concentrations of ABP were measured in testis, efferent duct fluid (EDF) and segments of the epididymis from adult rats. Testis and epididymis segments were homogenised separately at 4° C in three volumes of 50 mM Tris HCl, pH 7.4, containing 1.5 mM EDTA, 0.5 mM 2-mercaptoethanol, and 10% glycerol. Homogenates were centrifuged at 105,000g for 60 min. Supernatants and EDF were extracted with charcoal (1 mg per mg protein) overnight at 0° C, to remove endogenous steroids and the charcoal removed by centrifugation. Total protein was measured in each sample by the method of Lowry *et al.*¹¹.

Binding capacity of ABP was measured by 'steady state' polyacrylamide gel electrophoresis (SS-PAGE)¹². By this method, 1,2-³H-5 α -dihydrotestosterone (³H-DHT) is dissolved in the acrylamide solution before it polymerises. ³H-DHT is thus distributed uniformly in the polymerised gel and remains stationary in the electrophoretic field until

Fig. 1 Concentrations of ABP in 105,000g supernatants prepared from segments of rat epididymis in comparison with rat testis (a), efferent duct fluid (EDF) (b), and serum (c). ABP was measured by steady state polyacrylamide gel electrophoresis (SS-PAGE). Samples were adsorbed overnight with dextran coated charcoal at 0°C (1 mg Norit A mg⁻¹ protein). Charcoal was removed by centrifugation twice at 10,000g in a Beckman microfuge, and samples of 100 µl were layered onto 6.5% acrylamide gels (5 × 70 mm) containing 10% glycerol, to which 2 nM ³H-DHT had been added before polymerisation. Electrophoresis was run at 0°C for 2 h, and 2 mAmp per tube was applied. Following electrophoresis, the gels were transversely sliced into 2.3 mm segments which are placed directly into counting vials with 10 ml toluene scintillation fluid. After standing overnight at room temperature, more than 98% of the radioactivity was extracted into the toluene. Steady state between bound and free ³H-DHT is obtained when the level of radioactivity in front of the ABP peak is identical to that behind the peak. At steady state the amount of ³H-DHT in the peak is a linear function of the total amount of binding protein (ABP) present in the sample: Total ABP = Peak ABP($K_D/[H] + 1$) where K_D is the equilibrium constant of dissociation and $[H]$ is the concentration of the ³H-DHT in the gel.

it is bound by protein moving through the gel. After electrophoresis, the gels are sliced and the radioactivity is measured in each slice. A steady state between bound and free radioactivity is reached when the level of free radioactivity behind the binding protein peak equals the level in front. The concentration of binding protein can then be determined (assuming one binding site per protein molecule).

The concentration of ABP in EDF expressed as ³H-DHT binding capacity at saturation (pmol per mg protein) was much higher than in testicular and epididymal supernatants (Fig. 1). There was sufficient ABP in EDF to account for all the ABP measured in supernatants of testis and epididymis. Since the primary fluid from the seminiferous tubules becomes diluted before reaching the rete testis¹³, the concentration of ABP surrounding the germinal epithelium might be even higher than in EDF. The relatively large amount of ABP in caput epididymidis supernatant compared with testis supernatant, probably results from absorption of water as the testicular fluid passes through the efferent ducts and the first segment of caput¹⁴, and may also reflect a larger proportion of luminal fluid per unit of tissue weight. ABP concentration in epididymis supernatants decreases from segments I to V (Fig. 1). Further, the amount of ABP leaving the epididymis through the vas deferens is much less than that which enters into the caput, suggesting that the ³H-DHT binding activity of ABP is destroyed during passage through the epididymis. Although the exact role of ABP in the caput epididymidis is not yet known, it probably concentrates large amounts of androgen in the lumen close to the spermatozoa and surrounding epithelial cells. The concentration of endogenous DHT in

the caput epididymidis of rats (40–60 ng per g tissue)¹⁵ is several times higher than in any other body tissues so far examined, and is very similar to the concentration of ABP.

ABP production is stimulated by FSH

To establish the relationship between the production of ABP and maturational changes in the testis, ABP was measured in rats of various ages. At 1 and 2 weeks of age, testis and epididymis contained negligible amounts of ABP; at 3–4 weeks, however, increasing amounts of ABP were detected. After 4 weeks, ABP levels increased rapidly in the caput, reaching a peak at about the time of puberty (8 weeks) and decreasing in the adult to about 50% of the pubertal value¹⁶. Since the appearance of ABP corresponded with the onset of gonadotrophin secretion in the immature rat¹⁷, the effect of hypophysectomy on the levels of ABP was examined in rats at 5 weeks of age. Three days after hypophysectomy, the concentration of ABP in caput epididymidis supernatants was only about 40% of that in intact littermates, and by the 10th day, ABP had completely disappeared from both testis and epididymis. Evidence that this action of the pituitary is mediated through gonadotrophins, and not some other pituitary factor, was obtained by the injection of a human gonadotrophin preparation, containing both FSH and LH, to adult hypophysectomised animals. FSH-LH administration for 5 d caused a distinct increase of ABP in the testis supernatant (Fig. 2). The ABP concentration was more than 10 times higher than in the hypophysectomised controls and almost twice as high as in the intact littermates. These findings strongly indicate that ABP production is under pituitary control both in immature and adult rats.

Highly purified preparations of human FSH and LH were then used to examine their separate effects on ABP production. In 5-week-old intact rats, FSH injected subcutaneously for 10 d markedly increased the concentration of ABP both in the testis and the caput epididymidis, while LH treatment had no significant effect¹⁶. Similar results were obtained when rats were hypophysectomised at 5 weeks and started on daily injections of FSH 10 d later. After treatment for 10 d, FSH restored ABP levels in testis and epididymis supernatants¹⁶. When increasing doses of highly purified FSH were injected intramuscularly to immature rats, there was a linear increase in ABP concentration in caput epididymidis at doses between 2–10 µg of FSH

Fig. 2 Effect of FSH + LH treatment on ABP levels in rat testis. Adult rats in groups of four were hypophysectomised for 19 d. From day 20 after hypophysectomy, each animal was injected daily with 75 IU FSH + 25 IU LH or saline only. After treatment for 5 d, the testes were examined for ABP as described in Fig. 1. a, Sham operated; b, hypophysectomy for 19 d and saline for 5 d; c, hypophysectomy for 19 d and FSH + LH for 5 d. I, ABP; II, albumin. ABP, 100% in a, 14% in b and 157% in c.

Fig. 3 Specific stimulation of ABP by FSH. Rats in groups of four were hypophysectomised at 28 d of age and injected with 0.14 or 0.28 NIH units FSH-P₁ (total dose). The injections were started on day 30. Parallel groups of animals were injected with high doses of LH, thyroid-stimulating hormone (TSH), ovine prolactin (O-PRL), human growth hormone (HGH), testosterone propionate (TP) and oestradiol-17 β (E₂). Twenty times the maximum contamination of LH or O-PRL in 0.28 units FSH-P₁; (4 \times), four times the maximum contamination of TSH in 0.28 units FSH-P₁.

(ref. 18). Administration of testosterone propionate (TP) in increasing doses (10–100 μ g per 90 g body weight) to intact 50-d-old ('pubertal') rats caused a dose-dependent decrease in ABP concentrations in both testis and epididymis, indicating that ABP is sensitive to feedback suppression of pituitary gonadotrophins¹⁹.

FSH stimulation of ABP both in intact and hypophysectomised animals is specific, since no increase in ABP could be obtained using other pituitary hormones or sex steroids (Fig. 3). The sensitivity of the ABP response to FSH is comparable with that of the ovarian augmentation test^{20,21}. Significant stimulation of ABP in hypophysectomised animals was obtained with as little as 2 IU of FSH (equivalent to about 0.08 NIH units). The ABP response diminished with time after hypophysectomy but was restored by pretreatment with high doses of TP (0.5–16 mg TP per 90 g body weight) (unpublished observations). Similar augmentation of the ABP response to FSH was obtained by pretreatment with LH. The enhanced response to FSH following androgen priming is reflected in increased concentrations of ABP both in testicular and epididymal supernatants; however, it remains to be determined whether TP priming increases Sertoli cell production of ABP or decreases the rate of ABP degradation.

Androgen receptors in epididymal epithelium

After testosterone is taken up by epithelial cells of the epididymis, it is rapidly converted to several metabolites, with DHT and 5 α -androstane-3 α ,17 β -diol as major products^{22,23}. DHT is bound to intracellular androgen receptors in the cytoplasm^{24,25}, subsequently transported into the nucleus and bound to nuclear chromatin^{22,26}. DHT-receptor complexes can be extracted from epididymal nuclei in 0.4 M KCl and have a sedimentation constant of 3–3.5S (refs 22, 25 and 26).

Epididymal cytoplasmic receptor (CR) has physical properties and steroid specificity very similar to the ventral prostate receptor^{24,25,27}; both are highly specific for DHT. They also have similar electrophoretic mobilities by PAGE ($R_x = 0.4$), similar sedimentation rates by sucrose gradient centrifugation (8S and 4S) and similar elution volumes by Sephadex G200 gel filtration^{24–27}. Both are destroyed by heating at 50 $^{\circ}$ C for 30 min and lose binding activity after treatment with sulphydryl blocking agents, such as PCMPS (1 mM)^{24,25}. A characteristic feature of ³H-DHT-CR complexes of epididymis and prostate is the very slow rate of dissociation at 0 $^{\circ}$ C ($t_{1/2}$ 0 $^{\circ}$ C > 4 d) (refs 25, 27). This property clearly distinguishes ³H-DHT-CR from ³H-DHT-ABP,

which dissociates much more rapidly ($t_{1/2}$ 0 $^{\circ}$ C = 6 min) (ref. 25). The slow rate of dissociation of ³H-DHT-CR is consistent with a receptor function of CR. During the process of translocation from cytoplasm to nucleus, androgen is firmly bound to the receptor and cannot be exchanged by excess of free DHT (ref. 26). The rapid dissociation of DHT from ABP, however, suggests that ABP acts as a carrier protein capable of releasing its androgen to surrounding epithelial cells. A striking difference between ABP and CR was also found in their affinity for cyproterone²⁵. Cyproterone acetate inhibited the binding of ³H-DHT to epididymal CR to the same extent as it reduced uptake and binding by epididymal nuclei²⁵. Binding of ³H-DHT to ABP on the other hand was not affected by this treatment. These studies indicate that nuclear uptake and binding of DHT are dependent on CR and independent of ABP.

Androgen receptors in the seminiferous tubules

The evidence for androgen action on spermatogenesis prompted studies to discover androgen receptors in rat seminiferous tubules. Immature Sprague-Dawley rats hypophysectomised at 25 or 35 d of age were used. Three to twenty-four days after hypophysectomy, animals in groups of 10 or 20 were eviscerated, functionally hepatectomised²² and injected intravenously with ³H-testosterone. Whole testes or washed seminiferous tubules were homogenised in three volumes of 50 mM Tris HCl buffer, pH 7.4, containing 0.32 M sucrose and 3 mM MgCl₂ (TSM buffer); and 105,000g supernatants prepared similarly from epididymis and prostate. Binding was examined by PAGE (refs 6 and 8), Sephadex G200 gel filtration^{6,24}, and by sucrose gradient centrifugation^{6,24}.

Testicular cytosol fractions contained an androgen-protein complex moving as a symmetrical peak of protein bound radioactivity with an R_x of 0.4 (Fig. 4). The mobility of this androgen-protein complex was different from that

Fig. 4 Cytoplasmic receptors (CR) in testis (upper) and epididymis (lower) different from testicular androgen binding protein (ABP). Sprague-Dawley rats were hypophysectomised at 35 d of age. At different intervals afterwards (a, 3; b, 10 and c, 24 d) animals in groups of 10 or 20 were eviscerated and functionally hepatectomised²². Five ml of 5% glucose in water and 200 μ g cortisol were given subcutaneously 1 h before the operation. ³H-testosterone (91 Ci mmol⁻¹, 50 μ Ci) was then injected into the femoral vein, and the animals were killed after 3 h. Testis and epididymis 105,000g supernatants (100 μ l) were layered over 3.25% acrylamide gels (5 \times 60 mm) containing 0.5% agarose²⁵. Electrophoresis was run for 2 h at 0 $^{\circ}$ C and 1.5 mAmp per tube. After electrophoresis, the gels were sliced and counted as in Fig. 1.

of ABP ($R_s = 0.71$), but very similar to the CR of the epididymis and ventral prostate, which were run simultaneously for comparison. When the seminiferous tubules were separated from interstitial tissue, CR was present in the seminiferous tubular fraction. No androgen binding was detected in cytosol fractions of the interstitial tissue. Radioactivity bound to CR was eluted from the gel and identified by thin layer chromatography (TLC) and crystallisation of the isolated metabolites to constant specific activity. Only testosterone (60%) and DHT (40%) were bound to testicular CR, though these androgens were relatively minor fractions of the total labelled metabolites. Most of the radioactivity in the testis supernatant chromatographed with 5α -androstane- $3\alpha,17\beta$ -diol and more polar metabolites. In the same animals, the radioactivity bound to the epididymal and prostate CR was more than 90% ^3H -DHT.

Gel filtration chromatography of a similar aliquot of testicular supernatant yielded one peak of bound radioactivity in or close to the void volume of the Sephadex G200 column. The elution position of the steroid-receptor complex was similar to that of receptors in epididymis and prostate supernatants^{24,27}, but different from the ^3H -DHT-ABP complex which has a Stokes radius of 47 Å (refs 6, 7, 24). The bound radioactivity was extracted and again identified by TLC and crystallisation as testosterone (55%) and DHT (45%). Centrifugation of these supernatants through 5–20% linear sucrose gradients (sucrose solution in 50 mM Tris HCl, pH 7.4, containing 1 mM EDTA, 0.5 mM 2-mercaptoethanol and 10% glycerol) gave one nondisplaceable peak of bound radioactivity sedimenting as 6–8S.

To establish the receptor identity of CR in testis supernatant, the temperature stability and the dissociation of the androgen-protein complex were compared with cytoplasmic receptor in epididymis. Twenty animals, 25-d-old, were hypophysectomised and injected with ^3H -testosterone 3 d later. Testicular and epididymal 105,000g supernatants were heated at either 25° C or 50° C for 30 min, and binding analysed by PAGE. Androgen-CR complexes in

both testis and epididymis were stable after heating at 25° C, but were destroyed by heating at 50° C. Similar heat stability was found for the androgen-protein complex excluded from Sephadex G200 and the 6–8 S complex obtained by sucrose gradient centrifugation. This heat sensitivity was identical to that of the prostate cytoplasmic receptor^{24,25,27}, but different from that of ABP which was stable at 50° C (refs 6, 8, 24, 25). Dissociation of the labelled androgen-CR complexes was examined by PAGE after incubation of *in vivo* labelled supernatant with a large excess (10 µg) of unlabelled DHT for 2 h at 0° C. Dissociation of the androgen-CR complex in testis was negligible as was the dissociation of the androgen-receptor complex in epididymis. This extremely tight binding of androgen by the testis CR at 0° C ($t_{1/2}$ 0° C = 35 h) is similar to the binding by androgenic receptors in the epididymis and prostate, giving further support to a receptor function of testicular CR. Evidence for translocation of cytoplasmic androgen-receptor complexes into testis nuclei was obtained from the demonstration of androgen binding macromolecules in purified nuclei with steroid specificity identical to CR. These androgen-protein complexes could be extracted with 0.4–1 M KCl following injection of ^3H -testosterone and had a sedimentation of 3–4S.

Our results support the view that the germinal epithelium of rat testis is an androgen-dependent target tissue. The intracellular receptors for androgen demonstrated here probably mediate the androgenic stimulus to spermatogenesis. It is not yet clear which cells within the seminiferous tubules contain CR. Spermatocytes show typical 'target tissue' metabolism of ^{14}C -testosterone to DHT and 5α -androstane- $3\alpha,17\beta$ -diol²⁸. Also the formation of these metabolites by the rabbit testis is greatly reduced after selective destruction of the germinal cells of the seminiferous tubules by heat²⁹. The persistence of CR for as long as 24 d after hypophysectomy, however, indicates that CR is present in either Sertoli cells, spermatogonia or primary spermatocytes, since these were the only cell types remaining. To what extent the germinal epithelium cells are capable of retaining the CR-androgen complexes in their nuclei remains to be determined. Further studies are necessary to determine whether androgen acts directly on proliferating germ cells or stimulates spermatogenesis by an indirect action on the Sertoli cells.

The demonstration of androgen-receptor complexes in cytoplasmic and nuclear fractions of seminiferous tubules supports the concept that spermatogenesis is an androgen-dependent process. LH stimulates spermatogenesis by increasing androgen production by the Leydig cells. FSH stimulates production of ABP, presumably by the Sertoli cells, thereby increasing the binding and accumulation of androgen within the seminiferous tubules close to androgen-dependent cells of the epithelium (Fig. 5). ABP might, therefore, act as an essential androgen concentrating factor, which seems to be under control of FSH. In addition, FSH stimulation of ABP secretion into testicular fluid increases the amount of ABP (and androgen) transported to the caput epididymidis by the efferent ducts. Testosterone, which is taken up by epididymal cells both from the lumen and the circulating blood is 'activated' by 5α -reduction to form DHT. DHT bound to cytoplasmic receptors is transported into the cell nuclei where the androgen-receptor complex binds to chromatin and initiates metabolic processes which are necessary for sperm maturation. After releasing its bound testosterone to epithelial cells, ABP is free to bind testosterone or DHT which diffuses into the lumen from the blood or epithelium.

Financial support was given by the National Institutes of Health, World Health Organisation, Swedish Medical Research Council, and the Norwegian Research Council for Sciences and the Humanities. V.H. is a Fogarty International Postdoctoral Fellow.

Fig. 5 Schematic drawing of androgen action in the testis and epididymis. Testosterone (T) is secreted from the Leydig cells due to LH stimulation. Most of the testosterone is removed from the testis bound to different binding proteins in blood and lymph. ABP is produced by the Sertoli cells due to FSH stimulation and secreted into the seminiferous tubules. There, ABP generates a diffusion potential causing a net inflow of testosterone and accumulation of androgens. FSH also causes an increased secretion of ABP (and androgen) from the testis into the epididymis, by the way of the efferent duct fluid. Testosterone which enters the epididymis is activated by the formation of DHT. DHT bound to receptors is translocated to the cell nucleus, initiating the different metabolic processes necessary for sperm maturation.

Δ_4 Ad = Δ_4 -adione; 5α Ad = 5α adione; Ast = Asterone; 3β Ad = 3β adiol; Epi-andr = epiandrosterone

Nucleotide pyrophosphatase, a sialoglycoprotein located on the hepatocyte surface

W. H. Evans

National Institute for Medical Research, Mill Hill, London NW7 1AA, UK

A sialoglycoprotein enzyme hydrolysing nucleotide pyrophosphate bonds is a major externally located component on the hepatocyte surface membrane.

MEMBRANE-BOUND enzymes play a paramount role in the control of cell metabolism. Enzymes located on the surface membrane occupy a crucial position for control of the interaction of cells with the external environment. To assess the role of cell surface membrane enzymes in metabolic regulation and cell surface phenomena, knowledge of the location of these enzymes, especially with regard to the outer or inner faces of the membrane is desirable. By using an enzymic technique¹ to label the surface membrane of isolated cells and a sub-cellular fraction derived from the liver cell surface, I show that nucleotide pyrophosphatase, an enzymic marker in plasma membrane isolation studies^{2,3}, is externally located on the hepatocyte.

Nucleotide pyrophosphatase was purified from liver plasma membrane as a sialoglycoprotein of molecular weight 130,000 and is a major constituent of liver plasma membranes⁴. The external location of the nucleotide pyrophosphatase accounts for the failure of nucleotides to enter the liver in metabolic experiments⁵⁻⁷. The fact that the nucleotide pyrophosphatase is on the outside of the cell, whereas the sugar transferases are on the Golgi apparatus^{8,9}, strongly suggests that mechanisms proposing a role for membrane transferases in intercellular adhesion^{10,11}, and the uptake of serum glycoproteins¹² are unlikely to be generally operative.

Iodination of liver plasma membranes

Plasma membranes were prepared from liver homogenates as a population of vesicular membrane profiles derived from the sinusoidal, canalicular and contiguous faces of the hepatocyte^{2,13,14}. They were labelled with ¹²⁵I by using the lactoperoxidase-catalysed iodination procedure in which H₂O₂ was generated by a glucose-glucose oxidase system¹. This iodination technique was shown to label specifically and covalently the external face only of erythrocytes, erythrocyte ghosts¹, liver 'microsomal' vesicles¹⁵, and lymphocytes¹⁶. Iodinated, washed liver plasma membranes were dissolved in sodium dodecyl sulphate, and the polypeptides separated, mainly on a molecular weight basis, by electrophoresis in flat sheets of polyacrylamide¹⁷. Figure 1a shows liver plasma membranes to consist of at least 30 polypeptides, of which about six of the components in the higher molecular weight range are glycosylated. Iodinated plasma membranes contained two major peaks of ¹²⁵I-radioactivity corresponding to glycosylated polypeptide bands of apparent molecular weight of 130,000 and 100,000 (Fig. 1b).

The enzymic identity of one of the major iodinated polypeptides in liver plasma membranes was established by copurification of ¹²⁵I-radioactivity and nucleotide pyrophosphatase activity peaks. Since the enzyme also hydrolysed phosphodiester linkages⁴, it was more convenient to monitor purification of the enzyme by measuring alkaline phosphodiesterase activity by hydrolysis of the artificial substrate thymidine 5'-monophosphate *p*-nitrophenol ester. Iodinated plasma membranes,

Fig. 1 Electrophoretic separation on polyacrylamide gels of iodinated liver plasma membranes (*a*, *b*) and isolated hepatocytes (*c*). Liver plasma membranes were prepared from 'nuclear' pellets by a rate zonal procedure¹³, or from a 'microsomal' fraction by density gradient centrifugation^{2,14}. Livers were dissociated by perfusion through the portal vein with hyaluronidase and collagenase²¹. Membranes (13 mg protein) or hepatocytes (1×10^7 cells) suspended in 0.8 ml phosphate buffered saline containing 5 mM glucose were iodinated with 0.4 to 0.6 mCi carrier-free ^{125}I for 15–30 min at 20°C in the presence of 100 μg lactoperoxidase (Sigma) and 24 μg glucose oxidase (Worthington Biochemicals)¹. Iodinated membranes (*a*, *b*) were washed six times by centrifugation in water, and then dialysed against water until the dialysate was free of radioactivity, before dissolving by heating in 2% sodium dodecyl sulphate–4 M urea–1% mercaptoethanol. Iodinated hepatocytes (*c*) were washed six times in phosphate buffered saline by centrifugation at 50g for 2 min and then suspended for 15 min at 37°C in 1 ml phosphate-buffered saline containing 1% deoxycholate and 25 μg DNase. The supernatant, containing 90% of ^{125}I radioactivity attached to the cells, was mixed with sodium dodecyl sulphate–urea–mercaptoethanol. Membrane polypeptides and extracts of cells were resolved by flat plate electrophoresis in 8.5% polyacrylamide gels equilibrated in 0.1% sodium dodecyl sulphate¹⁷. Plasma membrane polypeptides were stained for protein with Coomassie Blue and the bands densitometrically traced at E_{595} (*a*). Glycoproteins (hatched areas) were identified by using the Schiff periodate reagent¹⁸. Gels were then cut into thin slices of equal length with a blade and ^{125}I -radioactivity determined on a γ -counter (*b*, *c*). In the absence of lactoperoxidase, fewer than 5% of the counts were incorporated and no peaks of radioactivity associated with protein were present in gel separation of membranes or cells.

solubilised in the detergent N-lauryl sarcosinate¹⁸, were added to a Sepharose 6B column, and the resolution of ^{125}I -radioactivity, protein and two plasma membrane marker enzyme activities—phosphodiesterase and 5'-nucleotidase followed (Fig. 2). A close coincidence between a peak of radioactivity and of phosphodiesterase activity was observed. Column fractions corresponding to the phosphodiesterase and 5'-nucleotidase peaks were pooled, concentrated and analysed by polyacrylamide gel electrophoresis. Figure 3*a* indicates that the phosphodiesterase activity peak corresponds to the ^{125}I -radioactivity peak of molecular weight 130,000 present in plasma membranes (Fig. 1*a*, *b*). The 5'-nucleotidase activity peak from the column that overlapped the trailing edge of the phosphodiesterase activity peak (Fig. 2) also contained a small ^{125}I -radioactivity peak of molecular weight 130,000 but the main peak of ^{125}I -radioactivity was at molecular weight 100,000 (Fig. 3*c*).

A sialoglycoprotein with dual specificity towards nucleotide pyrophosphate and phosphodiester bonds was purified from liver plasma membrane as a single band on polyacrylamide gels of apparent molecular weight 130,000 (ref. 4). The above results, therefore, suggest that the enzyme was iodinated. But to examine more directly the relationship between the enzyme activities separated by gel filtration and peaks of radioactivity resolved on polyacrylamide gels, the two enzyme activity peaks collected from the Sepharose column were also electrophoresed in polyacrylamide gels equilibrated in buffers containing deoxycholate (Fig. 3*b* and *d*). Although the resolution of membrane components in gels equilibrated in deoxycholate-buffer was inferior to that obtained in sodium dodecyl sulphate-buffer as judged by protein staining, the major ^{125}I -radioactivity and phosphodiesterase peaks were coincident (Fig. 3*b*). But the major 5'-nucleotidase activity peak did not coincide with the ^{125}I -radioactivity peak of molecular weight 100,000 (Fig. 3*d*).

The overall results show that the alkaline phosphodiesterase-nucleotide pyrophosphatase of liver plasma membranes was iodinated by the adopted procedure, since enzyme activity, ^{125}I -radioactivity and the molecular weight determined independently on purified enzyme were coincident. The liver plasma membrane fraction prepared consisted of closed vesicles. Studies with similar vesicles of a liver microsomal fraction have shown that they are impermeable to lactoperoxidase, and only proteins on the external face of the microsomal membrane were iodinated¹⁵. One may conclude, therefore, that the sialoglycoprotein functioning as a phosphodiesterase-nucleotide pyrophosphatase is located on the outer surface of the liver plasma

Fig. 2 Gel filtration on a Sepharose 6B column of a sarcosyl extract of iodinated liver plasma membranes. Iodinated membranes were extracted with a 4% sarcosyl, 2.1% Tris buffer pH 7.9^{18,19}, and the extract, after concentration by pressure filtration across Diaflow XM50 filters, was resolved in a column equilibrated with 0.2% sarcosyl buffer. Column fractions were assayed for protein at E_{280} (\blacktriangle), ^{125}I (\circ), 5'-nucleotidase (\bullet) and alkaline phosphodiesterase (\blacksquare) activities. The activity peaks of phosphodiesterase (tubes 35–39) and 5'-nucleotidase (tubes 42–48) were concentrated by pressure filtration across Diaflow UM50 filters.

*Phosphodiesterase or 5'-nucleotidase (arbitrary units).

membrane vesicles. Carbohydrate chains of glycoproteins are externally orientated on surface membranes¹⁹, and the liver plasma membrane contains sialic acid on its outer surface²⁰. It is highly likely that the plasma membrane vesicles used in the present study were of a normal 'right side out' orientation, but to obtain further evidence for the external location on the liver surface membrane of the labelled sialoglycoprotein enzyme, free hepatocytes were prepared and iodinated in the same manner.

Iodination of isolated hepatocytes

Perfusion *in situ* of rat liver through the portal vein with a Krebs-Ringer medium containing collagenase and hyaluronidase dissociates the lobules into cells²¹. Hepatocytes, separated from the Kupffer, endothelial and other cells by repeated low-speed centrifugation, were iodinated as described for the plasma membrane fraction¹. The iodinated cells were briefly incubated in a medium containing deoxycholate and the extracts then analysed by polyacrylamide gel electrophoresis in sodium dodecyl sulphate-buffer (Fig. 1c). Many peaks of ¹²⁵I-radioactivity were obtained, and one major peak corresponded in its molecular weight position to one of the two major iodinated peaks obtained with isolated plasma membranes. The coincidence in molecular weight of a ¹²⁵I-radioactivity peak of apparent molecular weight 130,000 both in a plasma membrane subfraction and cells supports the conclusion that the phosphodiesterase-nucleotide pyrophosphatase is located on the surface of the hepatocyte. The presence of a greater number of labelled components on hepatocytes compared with isolated plasma membranes contrasts with the results obtained with iodinated erythrocytes¹. It may be caused by damage to the outer cell surface of the hepatocyte occurring during the enzymic treatment used to dissociate the tissue, or to the presence on the cells of tightly-adsorbed nonmembrane proteins.

Implications for membrane functioning

To resolve the molecular basis of events occurring at the cell surface, a number of chemical²² and enzymically catalysed labelling reagents^{1,23} have been used to identify molecules externally located on the surface membrane. These studies, initially made on erythrocytes²³ and later extended to include platelets²⁴, fibroblasts²⁵, lymphocytes^{16,26} and cultured cells^{27,28}, in general identify glycoproteins of high molecular weight among the labelled components. For example, lymphocyte and sarcoma ascites tumour cell plasma membranes possess a major protein of molecular weight 130,000 that was labelled by iodination^{26,29}. These studies do not, however, assign a direct functional role to the iodine-labelled cell surface membrane components. My experiments show that a glycoprotein component located on the outer face of the hepatocyte surface membrane possesses nucleotide pyrophosphatase activity.

The rapid degradation of nucleotides, for example, NAD, ATP, UDP-galactose by perfused livers^{5,7} is now explained. Hydrolysis by the blood sinusoidal surface membrane of sugar nucleotides yields nucleotide monophosphates which may be further degraded by nucleotide monophosphatases, for example, 5'-nucleotidase which, although not significantly labelled in the present experiments, was also shown by the use of antisera³⁰ and by cytochemical studies³¹ to be externally located on liver surface membranes. These enzymes may be components of a metabolic network of enzymes integrated to varying degrees into the surface membrane and functioning in the transport of nucleotides across the cell surface.

Cell surface galactosyl transferase activity transferring galactose from sugar nucleotides to galactosyl acceptors has featured in proposed intercellular contact mechanisms^{10,11} and the enzyme was also implicated as a binding site on liver plasma membranes for asialoglycoproteins¹². But subcellular fractionation studies of the liver have clearly distinguished between

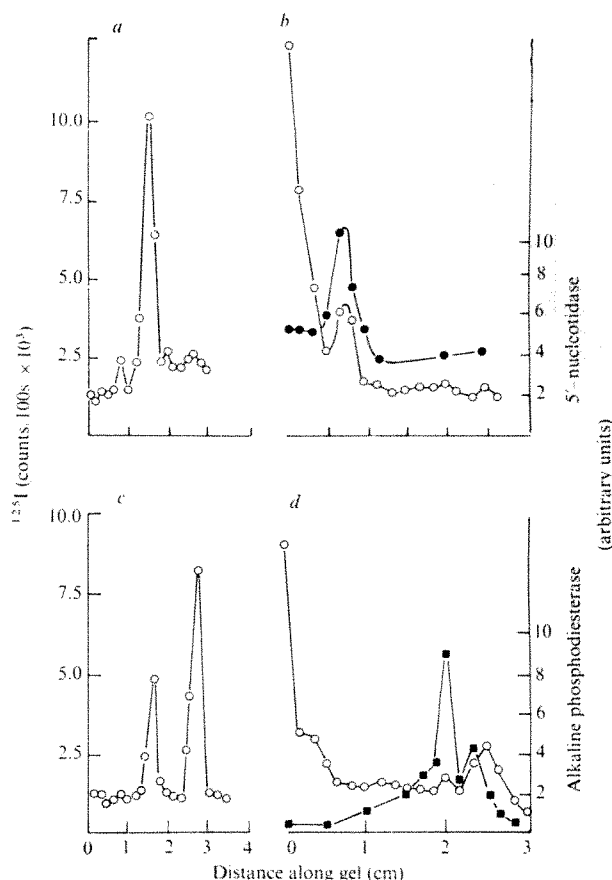

Fig. 3 Polyacrylamide gel electrophoresis of the alkaline phosphodiesterase (a, b) and 5'-nucleotidase (c, d) activity peaks separated by gel filtration (Fig. 2). The concentrated samples were electrophoresed in gels equilibrated in Tris-glycine buffers containing either sodium dodecyl sulphate (a, c) or deoxycholate (b, d)⁴. Enzyme activities (expressed as arbitrary units) were determined on dispersed gel fragments after determination of ¹²⁵I-radioactivity (○).

Golgi and plasma membrane fragments^{8,9} and shown that galactosyl transferases are Golgi enzymes and are not significantly located on the plasma membrane. Therefore in liver, and probably other cells, galactosyl transferases are not directly involved in cell surface phenomena. My results reinforce this conclusion, since even if some transferases were on the cell surface, the presence of the nucleotide-phosphatase would ensure a rapid disappearance of the transferase substrates, unless a lateral topographical separation of enzymic activities was invoked. Nucleotide pyrophosphatases-alkaline phosphodiesterases have been detected on a number of mammalian surface membranes^{3,32,33} and such an enzyme is probably one of the surface components of approximate molecular weight 100,000 shown to be iodinated on various cells. But the generalisation that this enzyme is always located externally on the cell surface membrane as currently shown for hepatocytes, must await copurification of enzymic and radioactivities in other cells and tissues. Cultured hamster cell lines were shown indirectly to contain an externally located surface membrane nucleotide pyrophosphatase, and the enzymic activity was absent in virally transformed cells^{31,34}. The present identification thus focuses on a molecular difference between normal and virally transformed cell lines of a cell surface sialoglycoprotein enzyme³⁵.

I thank Dr H. R. Perkins for advice and Mrs D. O. Hood and Mrs J. Stringer for assistance.

Sequence of a repressor-binding site in the DNA of bacteriophage λ

Tom Maniatis & Mark Ptashne

Biological Laboratories, Harvard University, Cambridge, Massachusetts 02138

B. G. Barrell & John Donelson

MRC Laboratory of Molecular Biology, Cambridge, UK

The sequence of 33 nucleotides immediately preceding the start point of transcription of an operon in bacteriophage lambda has been determined. This region includes recognition sites for lambda repressor and, probably, for other proteins. The sequence contains interdigitating symmetries.

Two loci on the DNA of bacteriophage λ —the operators—contain multiple repressor binding sites. Superimposed on each operator are sites recognised by a restriction endonuclease (Hin) and by *E. coli* RNA polymerase¹⁻⁵. At each operator (Fig. 1), repressor preferentially binds to a terminal site and the remaining sites are filled in the direction opposite to that of transcription of the adjacent controlled operon. Operator O_L , for example, controls leftward transcription of gene *N*. Repressor (probably a dimer)⁶ first binds to a 30-35 base pair site (S_1) proximal to *N*, and additional molecules (probably monomers) add sequentially to the right, filling five 15-base pair sites of lower repressor affinity. Each operator contains a single Hin target between the first and second repressor binding sites. At O_L , this site is located immediately to the right of S_1 . The region of each operator recognised by RNA polymerase includes or is immediately adjacent to the Hin site^{3,4}. O_L is not transcribed *in vivo* (ref. 7 and H. Lozeron, personal communication); the start-point of leftward transcription is to the left of S_1 .

We report here the nucleotide sequence of 33 residues between the Hin site in O_L and the start point of leftward transcription. We also confirm the sequence of the first 26 residues to the left of the transcription start point, originally determined by analysis of an RNA transcript (J. E. Dahlberg and F. F. Blattner, in preparation). We refer to this latter sequence as the

5' end of *N*, although it is not known where translation of *N* begins. We present here the essentials of our arguments and our conclusions; details of the sequence determination will be presented elsewhere.

Experiments and results

When λ DNA is digested with Hin, about 50 different double-stranded fragments are generated. One of these, which is about 1,125 bases long (Hin 1125) contains S_2 - S_6 , and another contains S_1 (Fig. 2)^{2,3}. We purified microgram quantities of Hin 1125 by gel electrophoresis, and used it to prime *de novo* synthesis of one strand of S_1 as follows. Denatured Hin 1125 was reannealed in the presence of approximately equimolar quantities of purified λ I strand DNA. The *r* strand of the annealed Hin 1125 was then extended into S_1 by incubating the mixture with *E. coli* DNA polymerase I in the presence of Mn^{2+} , ribo-CTP or ribo-GTP and the appropriate three deoxynucleoside triphosphates,

Fig. 1 Schematic representation of the λ operators and adjacent genes. The wavy arrows show the direction of transcription of the repressor-controlled genes *N* and *tof*. Two arrows indicate the order of repressor binding from the first sites (S_1 and S'_1) to the final sites (S_6 and S'_5) in O_L and O_R . The Hin cutting sites in O_L and O_R are indicated along with the number of base pairs within the operators on either side of each Hin cut. The repressor gene is *cl*.

Fig. 2 Schematic representation of primed DNA synthesis at the leftward operator O_L . The lines labelled l and r represent, respectively, the l strand of λ DNA and the r strand of the restriction endonuclease fragment Hin 1125. Repressor binding sites within O_L are designated S_1 – S_6 . The boundary between O_L and the start-point of transcription of gene N is indicated by the dashed vertical line. The varying lengths of *in vitro* synthesised DNA resulting from asynchronous chain growth are represented by the wavy lines. The restriction endonuclease (Hin) cleavage sites at the extremities of Hin 1125 are indicated.

one of which was labelled in the α position with ^{32}P . The *in vitro* product of interest was then released from the template-primer complex by Hin digestion followed by denaturation. In some cases the product was digested with RNase without Hin digestion. The labelled oligonucleotides were fractionated and

Fig. 3 *a*, Two-dimensional fractionation of the products of a restriction-fragment-primed DNA polymerase I reaction. A total volume of 250 μl contained: 12 μg purified λ l strand DNA¹⁸, 1 μg Hin 1125 DNA², 67 mM Tris-HCl, pH 7.4, 0.67 mM MnCl_2 , 1 mM 2-mercaptoethanol, 1 mM ribo-GTP, 0.025 mCi α - ^{32}P -dATP (100 Ci mmol⁻¹), 0.05 mM dTTP, 0.05 mM dCTP, 20 μl DNA polymerase I (approximately 1–5 units). The reaction was started by the addition of DNA polymerase and incubated at 8° C. After 30 min the reaction mixture was extracted with phenol, and residual phenol removed by several ether extractions. The products were dialysed overnight against Hin buffer^{2,3}. To release the newly synthesised DNA from the restriction fragment, the sample was digested for 2 h with exonuclease-free Hin prepared as described previously³. The sample was precipitated by the addition of 1/10 volume 3 M sodium acetate and two volumes of ethanol. The precipitate was taken up in 5 μl of H_2O , sealed in a capillary, heated to 100° C and cooled in an ice bath. The denatured sample was fractionated in the first dimension by electrophoresis on cellulose acetate in a pH 3.5 buffer containing 5 mM EDTA and 7 M urea. The second dimension was homochromatography using a 7% unhydrolysed RNA mixture. The approximate chain lengths of the products are shown. *b*, Two-dimensional fractionation of an RNase digest of a ribo-G-substituted oligonucleotide. The sequences of the various products are indicated on the figure. The primary product, about 40 bases long, was eluted from the homochromatography plate of (a) and digested overnight with 5 μl of a solution containing 10 mg ml⁻¹ RNase T_1 in 0.05 M Tris-HCl, pH 7.4, and 0.005M EDTA. The digest was fractionated as in (a) except that a 3% RNA mixture hydrolysed for 30 min was used in the second dimension.

their sequence was determined using methods described by Sanger *et al.*⁸.

A typical experiment was as follows. The product of a Hin 1125-primed synthesis, polymerised from rGTP, dTTP, dCTP and ^{32}P -labelled dATP, was separated from the template primer complex by Hin digestion and subjected to two dimensional fractionation (Fig. 3). The homochromatography mixture used in the second dimension separates oligonucleotides of lengths about 1–80 bases. The products seen in Fig. 3a have a common 5' end (produced by Hin digestion) but differ in the 3' ends because of asynchronous growth of the chains. Each fractionated product was eluted, digested with ribonuclease T_1 , and again subjected to two-dimensional fractionation. Figure 3b shows a fingerprint of the oligonucleotides generated by RNase T_1

Fig. 4 Two-dimensional fractionations of snake venom exonuclease (a) and spleen exonuclease digests (b) of the 15-base long ribo-G terminated product, A-C-A-T-A-A-T-A-C-C-A-C-T-rGp. The digests were fractionated as described in the legend to Fig. 3. From the distance and angle of shift between a digestion product and that product with one base removed the identity of the removed base can be determined⁸. The nucleotide removed is shown between each product. Thus the venom exonuclease digestion gives a 3' sequence of A-A-A-T-A-C-C-A-C-T-G and the spleen exonuclease gives a 5' sequence of A-C-A-T-A-A-T-A-C. These two sequences contain the common sequence A-A-A-T-A-C. Digestion conditions were as follows. For venom exonuclease the sample was incubated first with 3 μl of a solution containing 10 mg ml⁻¹ bacterial alkaline phosphatase, 0.05 M Tris-HCl, pH 8.9, and 0.005 M MgCl_2 for 30 min at 37° C, to remove 3' phosphate. 4 μl of a solution containing 0.1 mg ml⁻¹ snake venom phosphodiesterase, 0.05 M Tris-HCl, pH 8.9, 0.05 M MgCl_2 was then added and the sample incubated at 37° C, and 1 μl aliquots were taken at 0, 15, 30, 45, 60, 90, and 120 min, frozen, and then pooled. For spleen exonuclease digestion was with 7 μl of a solution containing 0.1 mg ml⁻¹ spleen phosphodiesterase, 0.05 M citrate buffer pH 6.0. The reaction was treated as in (a).

digestion of one of these products, about 40 residues long. In this case the homochromatography mix used in the second dimension separates oligonucleotides of lengths about 1–20 bases. By comparing the fingerprints generated in this way from each of the Hin digestion products seen in Fig. 3a, the order of synthesis of various ribo-G-containing oligonucleotides, labelled with ^{32}P -dATP was determined. Finally, the sequence of the various ribonuclease T_1 products was determined by partial exonuclease digestion and by nearest neighbour analysis. Figure 4a shows a two-dimensional fractionation of a partial venom phosphodiesterase digest of an RNase T_1 product identified in the experiment of Fig. 3b. Figure 4b shows a partial spleen phosphodiesterase digest of the same product. (Venom and spleen phosphodiesterase attack, respectively, from the 3' and 5' ends of polynucleotide chains.) Inspection of these fingerprints reveals the following sequence, which was confirmed by nearest neighbour analysis (not shown):

5' G/ACATAAATACCACTG/G. 3'

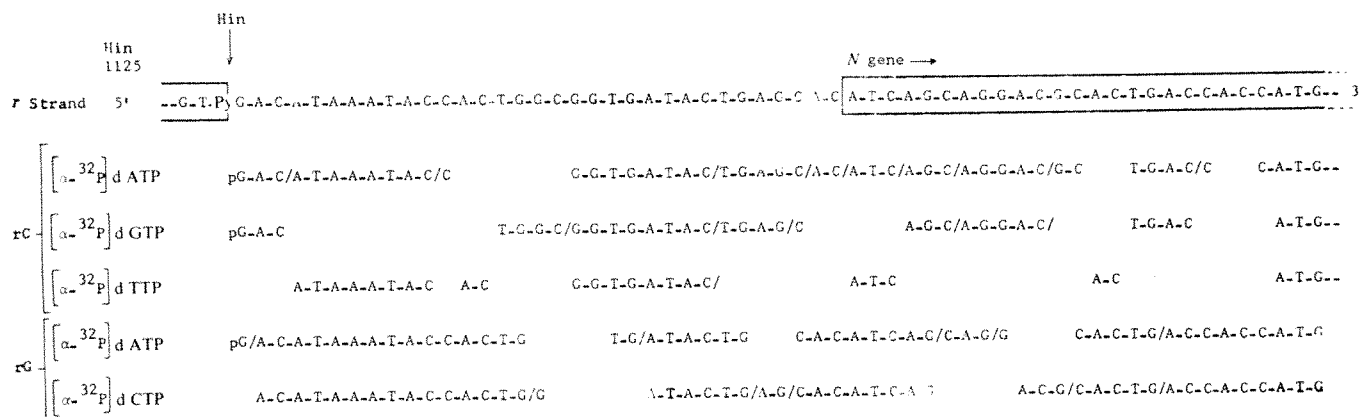

Fig. 5 The sequence from the Hin site of O_L to residue 26 beyond the startpoint of transcription of N . The sequences and order of synthesis from the Hin site of various ribo-C and ribo-G containing oligonucleotides are shown. The ribonucleotide triphosphate and the labelled deoxynucleotide triphosphate used in each reaction are indicated on the figure. Note that the orientation of the sequence is the reverse of that in Figs 2 and 6. See text for explanation.

The order of appearance and nucleotide sequence of each RNase digestion product are presented in Fig. 5. Note that in this figure the orientation of the sequence is the opposite of that in Fig. 6. This maintains the convention that oligonucleotides are written in the orientation 5'-3'. The complete sequence from the Hin site in O_L to N as well as that of the first 26 residues of N , deduced from this information, is also shown in the figure. The sequence GT Py (Py=pyrimidine, Pu=purine) to the left of the Hin cut in Fig. 5 has been added by inference from the fact that Hin II, one of the activities in our Hin preparation, is reported to recognise the sequence 5' GTPyPuAC 3' (ref. 10, and K. Murray, personal communication).

The sequence of a mutant operator was determined as follows. Experiments were performed using as primer wild type Hin 1125 and as template / strands isolated from λ 101. This phage bears a mutation that decreases the affinity of S_1 for repressor^{2,3}. We found a single base difference between the wild type and λ 101 sequences. The sequence ATAAATAC in wild type DNA is replaced in λ 101 DNA with ATAAATGC.

Interesting aspects of sequence

The complete double stranded sequence of the region between the O_L Hin site and the beginning of N is shown in Fig. 6. Because RNA polymerase binds to the Hin site³⁻⁵, the maximum number of base pairs separating bound polymerase from the transcription start point is 33. This value is consistent with our

previous estimate³ and is considerably less than that suggested by Blattner *et al.*¹⁰. A revised estimate from Blattner *et al.* (personal communication) agrees with our data. DNA-bound polymerase is reported to cover 40 base pairs¹¹, and so it is possible that polymerase bound to the Hin site extends to the transcriptional start point.

There are three axes of two-fold rotational symmetry in the sequence in Fig. 6: at nucleotide 17 (Fig. 6a), between residues 15 and 16 (Fig. 6b), and at residue 14. In *a*, 16 of 24 residues are perfectly symmetric and 6 of the remaining 8 show pyrimidine-pyrimidine or purine-purine symmetry. In *b*, 14 of 26 residues are perfectly symmetrical and 6 of the remaining 12 show Py-Py or Pu-Pu symmetry. In *c*, 14 (or 16) of 30 are perfectly symmetrical while 12 of the remaining 16 (or 10 of the remaining 14) show Py-Py or Pu-Pu symmetry. We calculate the probability that a region containing the symmetry properties of configuration *a* or *c* appears by chance in a sequence of 35 base pairs is less than 1%; for configuration *b* the probability is perhaps a few percent. Analysis of the pyrimidine tracts of the smallest fragment protected from nuclease digestion by repressor¹ suggests that the minimal region covered by repressor extends from about five residues to the right of the Hin target to residue 30. All three symmetries lie within this region. The O^c mutation at position 10 lies in two of the symmetry regions, but we cannot say which of these symmetries (if either) is recognised by repressor. In the *lac* operator O^c mutations have been found in bases

Fig. 6 Symmetries in the region between the Hin site in O_L and gene N . The bases in boxes are symmetric about two-fold rotational axes indicated by vertical arrows. An operator mutation at position 10 is indicated.

comprising a symmetric sequence, as well as in interspersed bases which do not contribute to the symmetry¹²⁻¹⁴.

Why (other than fortuitously) should there be three overlapping (interdigitating) symmetries between the O_L Hin site and N ? One intriguing possibility is that these symmetries are recognised by different regulatory proteins—'multiplexing', as R. Pollack calls it. For example, the *tof* gene product is believed to act at O_L because a mutation which reduces the affinity of O_L for repressor also decreases the effect of *tof* product on leftward transcription¹⁵. RNA polymerase and N -product are two other proteins which might recognise these symmetries^{16,17}. We note that it is much more difficult, if not impossible, to construct interdigitating symmetries using perfect as opposed to hyphenated symmetries such as those seen in Fig. 6. Sequence analysis of the remaining sites in the operators and localisation of various regulatory mutations should provide a clearer understanding of the significance of these symmetries.

We thank Andrea Jeffrey, Debbie Gernes and Gloria Procopio for technical assistance, Fred Sanger for laboratory space and encouragement, and Dr R. Lehman for DNA polymerase. This work was supported by grants from the US National Science Foundation, the Guggenheim Foundation, the European Molecular Biology Organization, and the Medical Research Council.

letters to nature

High velocities and cocoon stars

LARGE scale gas movements with velocities of the order of 50 km s^{-1} giving rise to split, asymmetric or broadened emission line profiles have been observed in many H II regions¹⁻⁴. Proposed explanations for these motions include supernova explosions within or near to the H II regions⁵, and the acceleration of their ionised material by relativistic particles⁶ or by massive stellar winds⁷⁻⁹. I suggest that the breakup of the neutral gas and dust shell around a cocoon star could conceivably also produce high velocities. The existence of cocoon stars seems fairly well established from observations of infrared point sources^{10,11} and these are frequently associated with compact H II regions¹² and OH masers. Kahn¹³ investigated the evolution of a cocoon star and found that a star which accretes matter will form a false photosphere with a radius of the order 10^{13} cm and no appreciable H II region, provided that the rate of accretion exceeds approximately 10^{20} g s^{-1} . Around the false photosphere is a dust-free region with a radius of about 10^{16} cm , which corresponds to the radius at which refractory particles melt. At accretion rates of less than 10^{22} g s^{-1} the radiation pressure on the dust becomes powerful enough to stop the infall of matter and to drive a shock wave into the accreting gas flow outside a radius of 10^{16} cm . This situation is Rayleigh-Taylor unstable, and the shell will break up into globules. Consider a portion of neutral material with a density of $M \text{ g cm}^{-2}$, at a distance, R , from a star with mass, M_* , and luminosity L_* ($M_* \approx 6 \times 10^{34} \text{ g}$, $L_* \approx 6 \times 10^{38} \text{ erg s}^{-1}$). If the radiation force just balances the gravitational force exerted by the star, then

$$M = L_* (4\pi c G M_*)^{-1} \quad (1)$$

Thus, $M \approx 0.7 \text{ g cm}^{-2}$ independent of distance. This is very close to the surface density required by the models of Dyson¹⁴ ($M \approx 2 \text{ g cm}^{-2}$) for which a great deal of observational

evidence^{15,16} has been collected, particularly in the case of M8 and M42. It is thus possible that some of the globules represent the material that was just balanced by the radiation—gravitational forces, at the time of the breakup of the cocoon.

Next, consider the period of the onset of instability, when the accretion rate drops below 10^{22} g s^{-1} . The false photosphere will break up in certain directions according to a time scale given approximately by the free-fall time from a radius, R ($\approx 10^{16} \text{ cm}$) to the star. That is about 10^{10} s . Thus, an H II region is formed very soon after the onset of the instability which quickly spreads through the dust-free cavity around the star. An estimate of the properties of the H II region can be obtained.

The density distribution of a freely falling gas cloud in steady flow is given by

$$\rho(R) = \dot{M} (32\pi^2 G M_*)^{-1/2} R^{-3/2} \quad (2)$$

where \dot{M} is the accretion rate. Putting $\dot{M} = 10^{22} \text{ g s}^{-1}$ and integrating out to $R = 10^{16} \text{ cm}$, the density in the initially formed H II region will be of the order of 10^8 cm^{-3} and the total mass involved will be of the order of $2 \times 10^{32} \text{ g}$. This 'ultra-compact' H II region could not be contained by the overlying neutral material, and so would punch a hole (or holes) through those parts of the cloud with the lowest density, finally allowing the ionised material to escape more or less unimpeded.

The expansion of the ionised gas can be regarded as virtually isothermal, and so the ratio of the velocity, V , attained by a mass element and the sound speed, V_s , in the gas will be approximately given by:

$$V/V_s = (2 \ln(\rho_i/\rho_f)/3)^{1/2} \quad (3)$$

Where ρ_i is of the order 10^8 cm^{-3} and ρ_f is the final density, which is put equal to the density of a typical H II region—about 10^3 cm^{-3} . Thus, velocities of the order of three times the speed of sound should be attained along rather directional

streams. This is sufficient to explain the high velocities observed in a small fraction of the nebular material.

Long term periodicities in the sunspot cycle

THE existence of a long period undulation (~ 179 yr) in the solar cycle (Fig. 1, based on data from Waldmeier^{1,2}) is suggested by the planetary theory of sunspots. Jose³, for example, postulated an association between the 178.8-yr periodicity in orbital positions of the planets and the phase of the solar cycle. Wood⁴ used the presumed existence of a cycle of 170–180 yr in solar activity to predict the peak dates of future sunspot cycles. Our work indicates that although a 179-yr periodicity does exist in the sunspot cycle, it is not caused by a primary long term excitation function but is, instead, a beat phenomenon. This can be seen by computing the spectrum for the data shown in Fig. 1.

Burg (unpublished; see also ref. 5) suggested a method for estimating the spectrum of a time series that is based on an autoregressive description of the data to be analysed. This method, 'maximum entropy spectral analysis' (MESA), yields a result consistent with the information of the data and nothing more. We used this method in our initial analyses of the sunspot cycle.

Fig. 1 Twelve-month running mean sunspot numbers (1750–1971), based on data given by Waldmeier^{1,2}

Because the quality of early sunspot data is considered suspect by Waldmeier¹, we first analysed only data acquired after 1800. Specifically, for reasons related to computational procedures, we computed the spectrum for the 12-month running mean sunspot numbers from 1844 to 1971. The

Fig. 2 Maximum entropy spectrum for the data interval 1844–1971.

MESA spectrum (Fig. 2) suggests that no significant power is present at periods greater than about 110 yr. The spectrum is dominated by three peaks with periods of about 110, 10.9 and 9.7 yr. Further, we note that the spectral components with periods 10.9 yr and 9.7 yr are separated in frequency by about $0.012 \text{ cycle yr}^{-1}$, and so the two sinusoids interfere with one another to produce beats with a period of roughly 167 yr. The similarity in behaviour of cycles 1, 2 and 3, and of cycles 17, 18 and 19 (Fig. 1) is apparently caused by this beat phenomenon.

That a long term periodicity can be observed in the data lends credence to the sunspot observations between 1750 and 1850. Therefore, we computed the MESA spectrum for a set of data which included the early mean sunspot observations. That analysis, which used 214 yr of data (1750–1963), yielded a spectrum with significant

Fig. 3 Maximum entropy spectrum for the data interval 1750–1963.

signatures at periods of 95.8, 11.0 and 9.8 yr (Fig. 3). The frequency separation for the 11.0 and 9.8 yr spectral components yields an estimate of 181 yr for the long term periodicity. The similarity between the MESA spectra for the more recent sunspot observations (1844–1971) and the data incorporating the early observations (1750–1963) suggests that the sunspot data from 1850 to the present probably belong to the same population. This observation differs from the results of McNish and Lincoln⁶, who hypothesised that the very early data and the more modern data belong to two statistically different populations.

To refine our determination of the frequency separation between the 11.0 and 9.8-yr spectral components, we used all of the sunspot observations shown in Fig. 1 and correlated these data with a suite of sinusoids finely spaced in frequency about the peak frequencies in the 214-yr maximum entropy spectrum. The best correlations occurred at frequencies which correspond to periods of 11.2 and 9.9 yr. The actual frequency determinations for these correlation peaks are separated by $0.01116 \text{ cycle yr}^{-1}$, and as such, using this method the estimated period for the long

term undulation is 179 yr. This determination is in agreement with the average elapsed time between the peaks of cycles 1 and 17, 2 and 18, 3 and 19, and 4 and 20. Thus, although we estimate the length of the long period undulation in the sunspot cycle to be between 179 and 181 yr, we favour the 179-yr determination. This is somewhat longer than the 160–170 yr periodicity that Schöve⁷ observed in his data. On the other hand, our estimate is roughly 11 yr shorter than that of Cole⁸, who observed a 190-yr phase variation in Schöve's data. Regardless of these differences, the existence of a long period (160–190 yr) variation in sunspot activity seems certain.

If the major characteristics of the sunspot cycle repeat every 179 yr then, by definition, the data are periodic outside an interval of this length. It should, therefore, be possible to compute a periodogram using data covering 179 yr which is very similar to maximum entropy spectra computed previously. For example, the spectrum for the interval 1793–1971 (Fig. 4), exhibits the same spectral characteristics found in maximum entropy spectra computer previously.

Fig. 4 Periodogram for the data interval 1793–1971.

We used the observation of the 179-yr periodicity to predict future sunspot activity. The ability to predict solar activity is important if efficient use is to be made of the high frequency spectrum for international communications. King⁹ has shown, however, that significant climatic features (such as droughts and unusually long growing seasons) may be related to the solar cycle; if such relationships can be established with certainty, long range weather forecasts can then be issued for agricultural planning purposes (see also ref. 10).

Sunspot activity could be predicted by taking the spectral components corresponding to the data for any 179-yr interval and then reconstructing the smoothed sunspot numbers in that interval. Then, by repeating the waveform outside the interval, smoothed sunspot numbers could be extrapolated forwards and backwards in time. This method was applied to the spectral components corresponding to the periodogram of Fig. 4 (1793–1971) together with a

Fig. 5 Twelve-month mean sunspot numbers. A: a, reconstructed (1793–1971); b, predicted (1972–2050). B, Predicted minus reconstructed (1793–1971).

component of 47.4 smoothed sunspots (components at periods of less than 4.5 yr were eliminated). That yielded the results shown in Fig. 5A. In the interval 1793–1971, the reconstructed waveform has an r.m.s. residual (Fig. 5B) of five 12 month running mean sunspots.

Because these extrapolations can be projected backwards as well as forwards in time (we have assumed that the data are periodic, with a period of 179 yr), it follows that the predictions for the interval 1750–1792 correspond to the estimated sunspot numbers in the interval 1929–1971. As a measure of our prediction capability, therefore, we compared our predicted mean sunspot numbers for major features of the sunspot cycle from 1750 to 1792 inclusive with the corresponding observed values (Fig. 6). Although the data suggest that our predictions for the smoothed numbers at sunspot maxima may be in error by up to $\pm 25\%$, and that the time estimates for the occurrence of sunspot minima and maxima may differ from the true times by up to ± 2 yr, the general agreement between the trends of the observed and the predicted sunspot numbers is considered to be good.

Using the data in Fig. 5A, several predictions can be made:

Fig. 6 Twelve-month running mean sunspot numbers (1750–1800). Solid curve, observed; dashed curve, predicted (1929–1971).

The current cycle, number 20, will exhibit a prolonged decay in sunspot activity, with a null-to-null period of nearly 13 yr. The activity of cycle 20 has already exhibited unusual decay behaviour by rising briefly, instead of falling continuously, in 1972. It seems plausible, therefore, that the next sunspot low will not be reached until after 1975, and possibly as late as the summer of 1977. At the minimum, mean sunspot numbers could be as low as 3.

Cycle 21 will have a rather broad peak, possibly reaching its maximum value late in 1982. Mean sunspot numbers for this peak may not, however, exceed 50. The sunspot minimum following cycle 21 should occur around 1988, and could exhibit smoothed sunspot numbers as low as 2.

Twelve month running mean sunspot numbers greater than 100 will not be observed again until approximately 2015. Thus, the next 40 yr may be characterised by relatively low sunspot activity as compared with the activity of the last 40 yr. This observation is supported by the results of Cole⁸.

We thank Professor E. J. Öpik and Mr G. Jacobs for their comments and suggestions.

Asymptotic structure in torsional free oscillation data for the Earth

THE eigenfrequencies, ${}_n\sigma_l$, of the torsional modes, ${}_nT_l$, of a spherically symmetrical, nonrotating, elastic, isotropic Earth model, are defined, for fixed wave number $k=(l+\frac{1}{2})/a$, by the eigenvalue problem

$$\mu \left[\frac{d^2 U}{dr^2} + \frac{2dU}{rdr} \right] + \frac{d\mu}{dr} \left[\frac{dU}{dr} - \frac{U}{r} \right] + \left[{}_n\sigma_l^2 \rho - \frac{l(l+1)}{r^2} \mu \right] U = 0$$

(where $U=U(r)$; $\mu=\mu(r)$; $\rho=\rho(r)$; $a \leq r \leq b$)

and by the (zero stress) boundary conditions

$$\mu = [dU/dr - U/r] = 0, \quad r=a, \quad r=b;$$

where μ denotes rigidity, ρ density, a the radius of the core and b the radius of the Earth¹.

Using the Liouville transformation,

$$U = r^{-1}(\rho\mu)^{-1/4} Z, \quad r = \int_a^s \mu^{1/2} \rho^{-1/2} dt + a,$$

the asymptotic behaviour of ${}_n\sigma_l$ can be expressed in the form

$${}_n\sigma_l^2 = (n\pi)^2 \gamma^{-2} + A\gamma^{-2} + B\gamma^{-2} n^{-2} + O(n^{-3})$$

for fixed l and suitably large n , where $\gamma = \int_a^b \rho^{1/2} \mu^{-1/2} dr$,

and A and B are constants which depend only on the shear velocity and the density in the mantle, and on the radius of the core.

By its definition, γ corresponds to the radial travel time of an S wave between the surface of the Earth and the core-mantle boundary. On the basis of the asymptotic formula given, γ can be approximated by:

$${}_n\gamma_l^{(m)} = \pi(2nm + m^2)^{1/2} ({}_n\sigma_l^2 - {}_n\sigma_l^2)^{-1/2}$$

for sufficiently small values of m , if second order effects in the asymptotic formula are negligible. The values of ${}_n\gamma_l^{(m)}$ obtained from this expression may thus be expected to reach an asymptote, which is γ , for a sufficiently large overtone number $n=n_0$. Though n_0 is a function of l , it will be approximately constant over a small range of l values. This has been verified extensively using model data. For a given l , we estimate n_0 as the overtone number n at which, and beyond which, the values of ${}_n\gamma_{l-k_1}^{(m)}$, ${}_n\gamma_l^{(m)}$ and ${}_n\gamma_{l+k_2}^{(m)}$ match sufficiently closely. For example, Fig. 1 shows values of ${}_n\gamma_l^{(m)}$ calculated from the Earth model HBI of Haddon and Bullen for $m=1$ and $l=2, 18$. The slight oscillations of the two curves about the asymptote in Fig. 1 indicate that second order

Fig. 1 Curves of ${}_n\gamma_l^{(m)}$ calculated from the Haddon and Bullen Earth model, HBI (ref. 2): I, $l=2$, $n=1$ to 49; II, $l=18$, $n=1$ to 49.

effects are not completely negligible in the asymptotic formula which applies to torsionals computed from the Earth model HBI (ref. 2). The structure in those second order effects is influenced by the position, size and sharpness of discontinuities in shear velocity, and by density in the mantle. The slight variation between the two curves for $n \geq 10$ is mainly because of numerical error in the computed periods.

The quantities γ and n_0 are obviously potentially important as constraints in the derivation of realistic Earth models by the inversion of torsional overtone data. Published observations of ${}_nT_l$ from free oscillation studies exist only for small overtone numbers², and calculations indicate that the asymptote has not been reached for these values of n . Some periods for ${}_nT_l$ up to $n=18$ have, however, been derived³ from data⁴ based on observations of the phase spectra of multiply-reflected S₀S waves. In particular, Brune and Gilbert³ list periods calculated for ${}_8T_{14}$, ${}_{12}T_{14}$, ${}_9T_{16}$, ${}_{14}T_{16}$, ${}_{10}T_{18}$, ${}_{16}T_{18}$, ${}_{11}T_{20}$ and ${}_{17}T_{20}$, with a standard error of approximately 1.2 s. Estimates of γ derived from these observations are listed in Table 1. The range of these four estimates is 1.22 s, and for the last three it is only 0.38 s. Despite the smallness of the sample, the consistency of these results strongly suggests that $n_0 < 10$ for $14 \leq l \leq 20$.

We have re-examined the data of Brune⁴ to see whether there is any additional information about the overtone structure. Included in example 4 of his Table 1 is a period of

Table 1 Values of ${}_n\gamma_l^{(m)}$ derived from the data of Brune and Gilbert

n	l	m	${}_nT_l$ periods (s)	${}_n\gamma_l^{(m)}$ periods (s)	${}_n\gamma_l^{(m)}$ (s)
8	14	4	109.64	75.81	469.30
9	16	5	97.18	65.10	470.14
10	18	6	87.29	75.03	470.44
11	20	6	79.27	53.54	470.52

147.659 s, which was not identified by Brune and Gilbert³, but which must correspond either to ${}_6T_{10}$ or ${}_6T_{11}$. Using Brune and Gilbert's³ periods for ${}_9T_{10}$ and ${}_{10}T_{11}$, this gives either ${}_6\gamma_{10}^{(3)} = 466.91$ s or ${}_6\gamma_{11}^{(4)} = 464.18$ s. Both are significantly smaller than the values of ${}_n\gamma_l^{(m)}$ in our Table 1, suggesting that $n_0 > 6$.

Brune and Gilbert acknowledge the possibility of bias towards continental values in the data, but point to the consistency with other normal mode data as an indication that there is no important regional bias. Although the value 470.36 s for the radial S time between the Earth's surface and the core-mantle boundary, obtained as the mean of the last three values in Table 1, does depend heavily on the 'structure' corrections applied by Brune⁴ to his data, the accuracy of the numerical calculation is unaffected. As far as the estimation of n_0 is concerned, we have found from model studies that the point at which the asymptote becomes discernible depends largely on the position, size and sharpness of discontinuities in the upper mantle, and that smoothing of the discontinuities tends to shift this point to smaller values of n . The periods of free oscillation modes are determined by the laterally averaged properties of the Earth, and it is certain that some smoothing of the velocity and density structure in the region of the discontinuities would result from this averaging process. Brune (personal communication) has pointed out that the Brune and Gilbert³ ${}_nT_l$ periods are strongly biased towards a model with no discontinuities, as a result of the fact that no reflections from any possible discontinuities were taken into account in the phase correlation. This no doubt accounts for the small scatter observed in the ${}_n\gamma_l^{(m)}$ values derived from these regional data. Our estimate of n_0 may therefore have to be revised when better data become available.

- Finally, we remark that the nature of the asymptotic structure in the ${}_nT_l$ periods will impose a quite delicate constraint on Earth models, especially in view of the effects of upper

mantle discontinuities noted above. An investigation of the significance of this constraint is now in progress.

We thank Professors A. L. Hales and J. N. Brune for comment, and Professors J. N. Brune and F. Gilbert for making data available before publication.

H₂SO₄-HNO₃-H₂O ternary system in the stratosphere

RECENTLY, Friend *et al.*¹ reported a comprehensive laboratory study of a system of air containing trace quantities of H₂O, SO₂, NH₃ and O₃. By varying the proportions of these trace gases and the conditions of radiation of ultraviolet light and temperature, they obtained some detailed information for studying the mechanism of formation of stratospheric sulphate particles. They proposed a chemical model to interpret their laboratory observations and other observed features of stratospheric aerosol. The possible role of nitric acid, however, which is relatively abundant in the stratosphere², was not included in their investigation of stratosphere aerosol formation. Also, the possible solid phase of 75% H₂SO₄ by weight in water at -50° C, as discussed by Toon and Pollack³, was not taken into consideration in their proposed chemical model to interpret the formation mechanism of ammonium sulphate or ammonium persulphate particles in the stratosphere. Toon and Pollack examined some of the physical properties of nitric acid, sulphuric acid and ammonium sulphate in stratospheric thermodynamic conditions³. Using physical equilibrium phase diagram analysis techniques⁴, they compared the equilibrium vapour pressure over nitric acid solutions with observed water and nitric acid partial pressures in the stratosphere, and concluded that nitric acid cannot be present as an aerosol in the lower stratosphere. For sulphuric acid, they predicted that sulphuric acid aerosol particles in the stratosphere are 75% H₂SO₄ by weight in water, in agreement with observations by Rosen⁵. From the freezing curve of H₂SO₄ solutions⁶, Toon and Pollack pointed out that H₂SO₄ (75% in weight)-H₂O (25%) aerosol particles should exist in the lower stratosphere either as a solid or as a supercooled liquid. If most of the stratospheric sulphuric acid aerosol particles are in the solid phase, then the chemical models for the formation of ammonium sulphate using solution chemistry in sulphuric acid would not be applicable.

Here we present an order of magnitude estimate for the equilibrium vapour pressure over the ternary system H₂SO₄-HNO₃-H₂O to study the possibility of stratospheric aerosol formation involving HNO₃. Figure 1 shows the schematic equilibrium phase diagram for the H₂SO₄-HNO₃-H₂O ternary system at -50° C. The percentage labels refer to

Fig. 1 Order of magnitude changes in vapour pressures for ternary system H₂SO₄-HNO₃-H₂O at -50° C. Vapour pressure curves are obtained by extrapolating from boiling point data. Each contour represents an order of magnitude change in vapour pressure. Note that in reading graph, weight percentages of the three components must add up to 100%. If graph is read incorrectly the sum will be 200%.

the % by weight. The total vapour pressure over the H₂SO₄-HNO₃-H₂O ternary system at -50° C is expressed as a function of the weight composition. The shaded area in the diagram indicates the lowest total vapour pressure region. To estimate the order of magnitude of these equilibrium total vapour pressure we have extrapolated the available data from the international critical tables⁷ to -50° C by using the Clausius-Clapeyron equation $dP/dT = L/Tv$, where P is the vapour pressure, T is the absolute temperature, v is the molar volume and L is the latent heat which is assumed to be constant over the temperature range. The vapour pressure obtained by this approximation will be larger than the values measured if the freezing point of these ternary systems is higher than -50° C, since the slope of the curve is proportional to L , and the curves will become steeper at the freezing point. From this crude approximation, we have found a region (Fig. 1, shaded area around 70-80% H₂SO₄, 10-20% HNO₃ and 10-20% H₂O) with the lowest vapour pressure. The vapour pressure in this region is about 10⁻⁴ to 10⁻⁵ times lower than the vapour pressure of 75% H₂SO₄ by weight in water. Toon and Pollack estimated the vapour pressure for 75% H₂SO₄ by considering the latent heat as a constant except at the melting point³ (-33° C). They found the vapour pressure for this composition at -50° C is about 10⁻⁴ mm Hg. For a supercooled liquid (without considering the freezing point) the vapour pressure for 75% H₂SO₄ at -50° C is about 10⁻³ mm Hg. Therefore, the vapour pressure of the shaded region is about 10⁻⁸ mm Hg or lower. We base this value on the vapour pressure of 75% H₂SO₄ rather than directly calculating it, because the vapour pressures calculated from ternary system data do not agree with binary system data⁷. This is also the reason why no numerical values for vapour pressure are presented in Fig 1. The curves are intended primarily to indicate the shape and depth of a region where aerosol growth is favoured. The accuracy of the results presented in Figs 1 and 2 depends upon two factors, the boiling point data for the ternary system⁷, and the accuracy of the extrapolation to -50° C. We feel that the results are accurate to within an order of magnitude.

For a more accurate estimate of the vapour pressure of this ternary system at -50° C, two factors should be taken

Fig. 2 Experimentally measured vapour pressure points of stratospheric aerosols determined from data obtained by Rosen¹. Also shown are vapour pressure curves for, *a*, the 75% H_2SO_4 -10% H_2O -15% HNO_3 ternary system, and *b*, the 75% H_2SO_4 -25% H_2O binary system.

into consideration. First, the latent heat L should be considered to be a function of temperature instead of a constant. In general, the latent heat decreases with increasing T , as it does for water. Then the vapour pressure at 50°C should be lower than what we have estimated. Second, the ternary system in the shaded region may exist as a solid. Since the vapour pressure of a solid is lower than that of a supercooled liquid at the same temperature, once again, our estimate for the vapour pressure could be too high. Therefore, as an order of magnitude estimate, it is probably safe to say that the vapour pressures for the ternary system H_2SO_4 - HNO_3 - H_2O with weight composition around 70-80% H_2SO_4 , 10-20% HNO_3 , 10-20% H_2O at -50°C are below the order of 10^{-8} mm Hg.

The measured partial pressure for HNO_3 in the stratosphere at -50°C (refs 2 and 3) is of the order of 10^{-7} to 10^{-6} mm Hg, for H_2O , the measured partial pressure is of the order 10^{-4} to 10^{-3} (ref. 3). Comparing the estimated total vapour pressure of the ternary system H_2SO_4 - HNO_3 - H_2O with the weight percentage mentioned above, there exists more than sufficient nitric acid and water vapour in the stratosphere to participate in ternary system aerosol formation at -50°C . Therefore, nitric acid should be found in stratospheric aerosols, provided H_2SO_4 is also present. Furthermore, we have compared the vapour pressure of the ternary system with data of stratospheric aerosols as observed by Rosen⁵ (Fig. 2). It is found that a ternary H_2SO_4 - HNO_3 - H_2O system with weight composition 75% H_2SO_4 , 10% HNO_3 and 15% H_2O , would conform to the experimentally determined vapour pressure curve as well as the one of 75% sulphuric acid solution fitted by Rosen⁵.

Because of the presence of HNO_3 , the freezing temperature of the sulphuric acid solution will be reduced. Based on the assumption of ideal solutions, we have estimated the decrease in the freezing temperature caused by adding 10% nitric acid to the sulphuric acid solution (with 75% H_2SO_4 and 25% H_2O). With the heat of fusion of 75% H_2SO_4 taken to be 4,360 cal mol⁻¹ (ref. 8), and the freezing temperature of the 67.5% H_2SO_4 , 22.5% H_2O and 10% HNO_3 ternary system is estimated to be -45°C . Since we have a real rather than an ideal solution, we expect the freezing temperature in the shaded region to be lower than -50°C .

We conclude that one cannot rule out the possibility that nitric acid may participate in aerosol formation in the stratosphere. More experimental measurements on the equilibrium vapour pressure for the ternary system H_2SO_4 - H_2O or other suitable ternary and multicomponent systems are strongly recommended. Furthermore, it is important that *in situ* measurements to determine whether stratospheric aerosol contain nitric acid are made.

We thank Professor V. A. Mohnen, Professor D. Stauffer and Drs I. Blifford, R. Drake, E. Martell and J. B. Pollack for comments. This work was supported by grants from NASA and NIH.

Potential method of geobarometry using quartz

As crystals grow from solution they may trap small amounts of the solvent and other solutes. It has long been known that minerals evolve gases on heating¹⁻⁴ and it has been assumed that, except for alteration during weathering, the gases are incorporated from the growth medium at the time of crystallisation. If the amount and composition of the gases trapped in minerals are to be used to make detailed geological interpretations it is essential that the location of the gas within the crystal structure is established. In minerals like carbonates and hydrates, 'gases' form part of the structure. Sites in which gas can occur include primary and secondary fluid inclusions, point defects, lattice dislocations, grain boundaries, and structure holes. Gas can also be adsorbed on crystal surfaces. Each site has its own characteristic temperature at which gas loss occurs, so that on heating a mineral the gases are released at different temperatures. This provides a method for distinguishing between gases from different sites.

Fig. 1 Water release from quartz as a function of temperature. The solid line indicates the total response. This is made up of separate contributions coming from: *a*, secondary fluid inclusions; *b*, primary fluid inclusions; *c*, surface adsorption; *d*, grain boundaries and lattice defects; *e*, lattice water.

We have studied the location of water in quartz, using a mass spectrometer to monitor the release of water as a function of temperature. Quartz samples (0.5 g) were heated in a vacuum in outgassed mullite or alumina tubes connected to a heated stainless steel gas handling system which formed the inlet to a calibrated mass spectrometer⁵. A resistance-wound furnace was used to attain temperatures of 25–1,250° C, and a gas-torch furnace was used for temperatures up to 1,850° C. All the studied quartz samples showed three major episodes of water release (Fig. 1). In the temperature range 100–450° C water comes from fluid inclusion and from surface adsorption. (The detailed experimental support for this conclusion will be published elsewhere.) The second peak at 1,150–1,300° C is attributed to water released from grain boundaries and dislocations as they thermally anneal⁶. The remaining water is present in point defects and is not released until the quartz lattice is destroyed by melting. No release of water was associated with the α quartz– β quartz (573° C), quartz–tridymite (867° C) or tridymite–cristobalite (1,470° C) transitions. The quantities of water which remain in the liquid when the quartz melts are unknown, but they seem to be insignificant. Infrared studies of the glass produced show no adsorption characteristic of OH or H₂O. As the water vapour released by the

Table 1 Conditions of growth for synthetic quartz crystals

Pressure (N m ⁻² × 10 ⁻⁸)	Pressure (pound inch ⁻² × 10 ⁻³)	Top temperature (° C)	Bottom temperature (° C)	Growth rate (mm d ⁻¹)
1.38	20	349	399	0.67
1.59	23	349	399	1.30
2.14	31	350	396	2.21
2.41	35	352	396	2.26
2.76	40	374	396	2.61
2.90	42	371	410	2.29
3.10	45	360	416	2.64

sample is continuously pumped away through the mass spectrometer the partial pressure of water vapour over the melt remains low, and because of this the equilibrium amount of water in the melt should also be very small.

We have studied seven synthetic hydrothermal crystals of quartz, grown at pressures of 1.38×10^8 to 3.10×10^8 N m⁻² (45,000 pound inch⁻²), (Table 1), and natural hydrothermal quartz crystals from Brazil and Arkansas. In all cases the release of water as a function of temperature resembled the trend indicated by Fig. 1. As expected, the amount of water in fluid inclusions varied widely, even within a single crystal, but the water which was evolved at about 1,200° C showed a much smaller range. The amount of water released on melting crushed pieces (≈ 3 mm³) of single crystals of synthetic quartz varied from 1.2 ± 0.2 to 5.8 ± 0.2 cm³ of water vapour per gram

of quartz. Duplicate determinations confirmed the value of $0.2 \text{ cm}^3 \text{ g}^{-1}$. There is a clear trend of increasing water content with growth pressure (Fig. 2), indicating that the water incorporated into lattice sites is related to the partial pressure of water at the time of crystal growth. The distribution coefficients range from 0.8×10^{-5} to 2.0×10^{-5} ml (STP) per g atom. These are probably minimum values. We have not yet done any experiments to determine the variation of the distribution coefficients with growth temperature or with the composition of the growth medium. It has been reported that the presence of Li⁺ in the liquid decreases the total water content of the quartz⁷ but the particular location of the water was not investigated. Growth rate varies with growth pressure (Table 1), so there is a trend of increasing water content of the lattice with increasing growth rate. The data are insufficient to resolve completely the influences of pressure and growth rate on the water content. We feel that pressure is the more important because the 2.76×10^8 N m⁻² (40,000 pound inch⁻²) and 3.10×10^8 N m⁻² (45,000 pound inch⁻²) crystals were grown at the same rate and have very different water contents. Also, the 2.14×10^8 N m⁻² (31,000 pound inch⁻²), 2.41×10^8 N m⁻² (35,000 pound inch⁻²), and 2.90×10^8 N m⁻² (42,000 pound inch⁻²) crystals were grown at similar rates but have different water contents, which vary as a function of growth pressure.

Fig. 2 Amount of water evolved from natural and synthetic quartz crystals between 1,650° C and the melting point, as a function of growth pressure. Values plotted at 1.38×10^8 N m⁻² (20,000 pound inch⁻²) and 3.10×10^8 N m⁻² (45,000 pound inch⁻²) are averages obtained from duplicate analyses. *a*, *b*, Water values obtained for the Arkansas and Brazilian quartz, respectively.

In most hydrothermal systems the partial pressure of water is approximately the same as to the total pressure, so a determination of the amount of water released at the melting point permits an estimate of the pressure at the time of crystal growth (assuming that the distribution coefficient is not appreciably altered by temperature, growth rate or composition of the growth medium). We have applied this potential method of geobarometry to the Brazilian and Arkansas quartz crystals, and it indicates pressures of 2.76×10^8 N m⁻² (40,000 pound inch⁻²) and 1.48×10^8 N m⁻² (21,500 pound inch⁻²) respectively. These values correspond to depths of 12,200 m (40,000 feet) and 6,550 m (21,500 feet), respectively, if the lithostatic pressure gradient has its usual value of 2.26×10^4 N m⁻² m⁻¹ (1.0 pound inch⁻² foot⁻¹). For a typical continental geothermal gradient of 30° C km⁻¹ these depths correspond to temperatures of 386° C for the Brazilian quartz, and 222° C

for the Arkansas quartz. If these temperatures and pressures are used to define a line of constant specific volume on a water phase diagram then the temperature at which the specific volume on a water phase diagram then the temperature at which the specific volume line intersects the two-phase boundary corresponds to the filling temperatures of the fluid inclusions. The calculated filling temperature for the Arkansas quartz is 138°C , which is in good agreement with the observed values of $100\text{--}150^{\circ}\text{C}$ (R. H. Konig, personal communication). For Brazilian quartz, filling temperatures ranging up to 190°C have been reported^{8,9}. The calculated value is somewhat high at 213°C . The calculated values were, however, obtained from the phase diagram for pure water and so they will be slightly higher than those calculated using data for saline solutions.

If the water content of the quartz lattice gives the partial pressure of water in the growth medium then this technique could probably be used with magmatic quartz to give the partial pressures of water in silicate melts. This method of determining partial pressures could also be extended to other minerals and to other gases if synthetic samples are available for calibrating the gas content as a function of the partial pressure in the growth medium.

We thank Western Electric for supplying the synthetic quartz crystals. The research was supported by a NASA grant, and by the University of Tulsa.

Fronts in the Irish Sea

A MARKED discontinuity in the sea surface temperature with horizontal gradients up to $1^{\circ}\text{C km}^{-1}$ is often observed in the western Irish Sea during the summer. This feature is the boundary between stratified and vertically mixed regimes¹. Here we describe observations by airborne radiation thermometer (ART) and conventional methods, and suggest a simple model accounting for the observed form and stable position of the front.

The region of low tidal energy to the west of the Isle of Man (IOM), (see Fig. 1) permits stabilisation of the water column by insolation during the early part of the summer. At the beginning of June stratification of this area is usually well established, and a rapid warming of the surface waters ensues. This leads to a sharp temperature discontinuity at

Fig. 1 Amplitude (m s^{-1}) of the discussed tidal streams (solid lines) in the Irish Sea at mean springs from Bowden¹. A, B, (heavy zigzag line), Observed positions of fronts. Depth contours are 100 m (dotted) and 50 m (dashed).

the surface, which may involve changes as large as 3°C in June and July. The temperature contrast is generally diminished in August as the temperature of the mixed regime approaches that of the surface layer in the stratified area. Strong horizontal temperature gradients remain, however, further down in the water column.

The position of the maximum surface temperature gradient, deduced from surface temperature surveys, is shown in Fig. 2. Surveys a–e are based on thermograph data supplemented by TSD stations. Coverage is limited as a result of the ship's slow speed (about 10 knots) and significant evolution of the temperature field resulting from surface heating and wind mixing may well have occurred during the survey. These difficulties preclude investigation of the detail form of the front from ship's observations alone, and we therefore proceeded to obtain alternative data using an ART. Surveys f and g (Fig. 2) represent results of ART surveys. In these two cases the position of the front has been corrected for tidal movements on the basis of the best available tidal stream data for the area. Errors which occurred in the earlier surveys because of tidal displacements, should not exceed 10 km.

The position of the front does not vary greatly (Fig. 2). With the exception of survey c all the observed positions lie within 10 km of a mean position. The front observed on this occasion was not well defined, and may have represented a transient condition during the establishing of stratification.

In aerial survey work, the radiation temperature of the sea surface is measured using a portable radiation ther-

nometer fitted to an aircraft. The instrument is calibrated in flight with a constant temperature black body, and simultaneous measurements of the true sea surface temperature at a depth of 3 m are made from a ship at selected points on the flight plan. With these controls the errors in the final estimate of sea surface temperature may be kept as low as $\pm 0.1^\circ \text{C}$. The aircraft operates at an altitude of approximately 150 m, from which the radiation sensor effectively samples an area of 50 m^2 of the surface of the sea.

Navigation is accomplished using the Decca Chain 3B/MP, with the operational legs flown approximately north-south along red lanes at intervals of $\sim 2 \text{ km}$ (3 Decca lanes). A tidal correction is applied to the data, which are then transformed on to a square grid with a mesh size of 2.54 km . This is accomplished for each grid point by meaning all the temperature values falling in a square of length 3.81 km which is centred on that point. The resultant smoothing helps to reduce the noise inherent in the raw data. Objective contouring is then accomplished by linear interpolation between adjacent grid points.

Figure 3a is the result of an ART flight on June 5, 1973. It shows a well developed frontal situation extending for almost 50 km through the survey area. The flight was made under nearly ideal conditions (clear sky, wind less than 10 knots) following a long period of almost calm weather. In the three days before the flight, the wind at Ronaldsway (IOM) did not exceed 15 knots and no winds greater than 20 knots were reported during the preceding two weeks. It therefore seems reasonable to assume that the observed position of the front represents an equilibrium undisturbed by wind mixing and transient motions produced by wind stress.

The relative stability of the front is also indicated by observations made by the aircrew during the flight. The pilot reported that the line of the front was clearly visible because of an accumulation of surface material in the vicinity of the maximum surface temperature gradient. The

Fig. 2 Position of the maximum temperature gradient in the boundary front A as deduced from sea surface temperature surveys. Date of measurements: a, August 18-21, 1969; b, June 15-19, 1970; c, June 7-11, 1971; d, July 12-15, 1971; e, June 26-30, 1972; f, August 24, 1972; g, June 5, 1973. a, b, c, d, and e, thermograph and TSD data; f, and g, ART data.

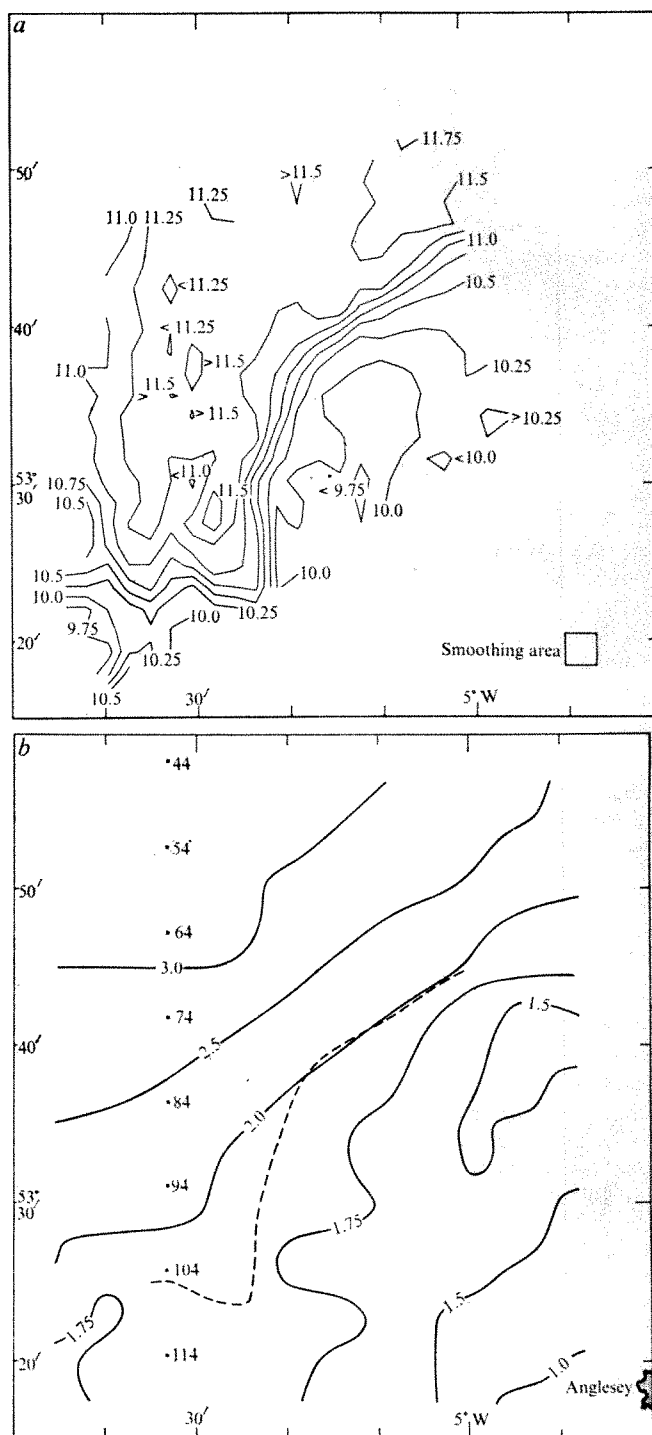

Fig. 3 a, Sea surface temperature distribution for June 5, 1973. Contours are at intervals of 0.25°C and have been drawn by an objective contouring programme. The data have been corrected for the observed difference between the radiation and thermograph temperatures of the sea surface. b, Contours of $\log_{10} h/u^2$ with h in metres and u in m s^{-1} . The dashed line shows the position of maximum gradient in Fig. 3a. The station positions shown (black squares) refer to the section shown in Fig. 4, which was worked in August 1970.

aircrew also noted changes in the colour of the sea and in the state of the sea as the front was crossed. The change in colour (greener in the mixed water, bluer in the stratified region) is probably a manifestation of the changes in the standing crop of phytoplankton in the frontal region. Estimates made in July 1971 indicate that the chlorophyll concentration decreases from $\sim 1.5 \mu\text{g l}^{-1}$ in the mixed water to $\sim 0.5 \mu\text{g l}^{-1}$ in the surface water of the stratified

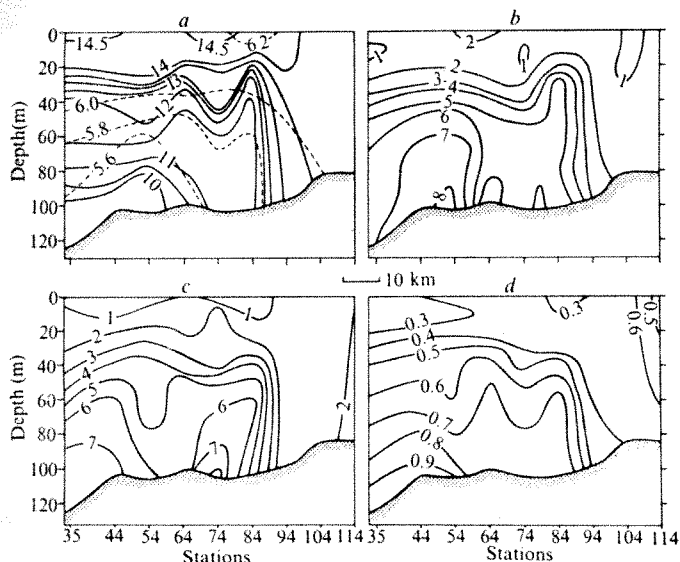

Fig. 4 North-south section across front A, showing the distribution of: a, temperature ($^{\circ}\text{C}$), (solid line), and oxygen (ml l^{-1} at NTP), (dashed line); b, silicates ($\mu\text{g atom silica l}^{-1}$); c, nitrate ($\mu\text{g atom nitrate nitrogen}$); d, phosphates ($\mu\text{g atom phosphate phosphorus}$). The positions of the stations are shown in Fig. 3b. Data taken August 17–20, 1971.

region. These changes in the standing crop of phytoplankton may be associated with limitations which are imposed by the availability of nutrients in the two regimes.

The distribution of nutrients in a section approximately perpendicular to the front is shown in Fig. 4 together with the corresponding temperature and dissolved-oxygen data. These results were obtained in mid-August 1971 but are representative of the distribution of nutrients throughout the summer months. The contrast in surface temperature is slight, but the front is clearly apparent in the intensified horizontal gradients below the surface mixed layer between stations 84 and 94. The distributions of all three nutrients, nitrate, phosphate and silicate, and the dissolved oxygen, are strongly correlated with the temperature structure. In the cases of nitrate and phosphate, the concentration in the mixed water (stations 104, 114) is generally higher than in the surface layer of the stratified regime, but large concentrations of all of the nutrients remain in the bottom water of the stratified regime, which is also characterised by depletion of the dissolved oxygen content. The higher values of nitrate and phosphate at the surface in the vertically mixed regime probably result from replenishment of nutrients from the bottom, which is not possible in the stratified area because vertical mixing is strongly inhibited.

The relative consistency of the observed position of the front suggests that the transition between stratified and unstratified regimes is essentially controlled by the level of tidal mixing. To examine this hypothesis we have considered the energetics of tidal mixing in a simple case.

Suppose that an amount, q , of heat is introduced into the surface of a water column of depth h , and an initial density ρ . This heat input produces a density change $\Delta\rho$ in a thin surface layer Δh . To mix the column vertically to a uniform density ρ' in a depth h' the potential energy must be increased by an amount $V_2 - V_1$ where

$$V_1 = \frac{1}{2} \rho g h^2 - \Delta \rho \Delta h g h + P h = \text{potential energy before mixing}$$

$V_2 = \frac{1}{2} \rho' g h'^2 + P h' = \text{potential energy after mixing; where } P = \text{atmospheric pressure.}$

Assuming that the density is a linear function of temperature, and neglecting salinity as a source of buoyancy input, then it is easily shown that $h = h'$ and

$$V_2 - V_1 = \alpha q g h / 2c$$

where α is the linear expansion coefficient and c is the

specific heat. For a rate of heat input Q , the demand for potential energy to maintain mixing would be

$$dV/dt = \alpha Q g h / 2c$$

Energy is lost from the tidal motion at a mean rate of

$$dE/dt = \tau_b u_b = k \rho |u_b|^3 = (4k/3\pi) \rho u_o^3$$

where u_b and τ_b are the velocity and shear stress respectively, near the bottom, and u_o is the amplitude of u_b . k is a constant in the assumed quadratic friction law. A fraction ϵ of this kinetic energy is considered to be available for increasing the potential energy of the water column so that at transition there is a balance defined by

$$h/u_o^3 = 8c\rho k\epsilon/3\pi\alpha g Q$$

If the area and time of interest are limited, Q can be regarded as constant. Then, providing ϵ and k are also constants, the locus of the front should be defined by a critical value of h/u_o^3 . Assuming that u_o is proportional to the observed surface tidal velocity amplitude u_s , h/u_s^3 can be used as the parameter which controls the formation of a front. Results for h/u_s^3 , based on the computations of a numerical model², are shown in Fig. 3b, along with the line of the front observed in June 1973. The front is approximately parallel to the contours of h/u_s^3 at a value between 65 and 100.

Assuming that ϵ and k are constant, this approach can be used to predict the occurrence of stratification and fronts for other parts of the continental shelf where the appropriate value of Q is known. As a more exhaustive test of our hypothesis we have a programme in hand to compare all the available data on stratification on the shelf, with the distribution of h/u_s^3 . We have already examined a front in the south-western approaches, the position of which (front B, Fig. 1) was predicted in this way. Observations in August 1972 revealed a transition occurring for $h/u_s^3 = 55$. Considering the uncertainties in u_s this value is not significantly different from that given for the A front. Provisional data for a less well defined transition in the Channel suggest a similar critical value of h/u_s^3 .

At present, relatively little is known of the residual velocity field in the vicinity of the front, largely because of the difficulties of making measurements of a velocity field which is being displaced tidally through an excursion of about 10 km. Observations with parachute drogues, which were tracked by radio in both the A and B fronts, show residual velocity vectors with speeds up to 10 cm s^{-1} approximately parallel to the front. Whether or not these velocities are generally in geostrophic balance with the density field remains uncertain on the basis of present knowledge. Such a balance is, however, suggested by data obtained in observations of the B front in August 1972, and if confirmed, would indicate longitudinal velocities of up to 50 cm s^{-1} in parts of the front.

We are grateful to Graham Savidge of the Marine Science Laboratories for the nutrient data in Fig. 4 and to the Meteorological Research Flight for providing the ART facilities.

Irregularities in dendrochronological calibration

Most of the 'wiggles' in the Suess curve¹, which is used for calibrating radiocarbon dates (denoted b.p.; sidereal dates denoted BP) in terms of dendrochronology, are likely to be artefacts². Curves with almost indiscernible fluctuations have been produced. There are, however, physical reasons for expecting some changes in the ^{14}C content of the atmosphere to have occurred and it is important to locate them by a method that does not depend either on intuition or on minimising deviations over the whole range of the curve⁴⁻⁶.

It should be possible to locate wiggles, if they exist, by using the estimated radiocarbon ages of samples themselves. If the samples have a uniform age distribution in sidereal time, then the apparent distribution in radiocarbon years would be uneven around the date at which the wiggle occurs; in other words, the apparent distribution of the samples in radiocarbon years would act as an indicator of the first differential of the slope of the calibration curve. Simulation trials showed that the uneven distribution can indeed be picked up, particularly if the sample ages are grouped at intervals which are small in comparison with the expected duration of the wiggle, but that the method is much more likely to be successful with a short lived sinusoidal irregularity than with a gradual but permanent change in slope. Stuiver (see ref. 7) has apparently tried a similar idea but his results are not available to us.

If the method is to be successful, there have to be enough sample ages available to ensure that, first, their distribution is uniform (although not necessarily constant) and, second that small regions of local high frequency are swamped. To meet these requirements we have considered all of the radiocarbon

Fig. 1 Frequency distribution of published radiocarbon dates. *a*, All dates; *b*, geological dates. In each case a smoothed curve has been constructed (see text).

dates recorded in volumes 1 to 15(2) of the journal *Radiocarbon*. All of the dates used had the half life of 5,570 yr; deep sea samples were omitted but pelagic shell samples were not, because there is some doubt about whether any correction is necessary for shallow waters^{8,9}. No attempt was made to separate samples from the southern hemisphere. 'Archaeological' and 'geological' dates were collected separately. We recorded approximately 13,800 archaeological, and 12,500 geological, dates going back 50,000 radiocarbon years.

The archaeological dates are not so suitable for testing, because almost all occur in the first 4,000 yr b.p. They will be discussed elsewhere, and here we report findings from the geological dates, and from the combined series, going back to 40,000 yr b.p.

A smoothed frequency curve was constructed by applying first-order smoothing algorithms (IBM SSP routines SE13 and SE15) successively to the grouped totals for intervals of 200 yr. From this a Kolmogorov-Smirnov statistic was calculated and was used to provide confidence limits¹⁰ for a curve corresponding to at least 150 dates, or extending over at least 150 yr. The sections were made to overlap, so that each decade interval had more than one chance of being in the centre of the sectional

Fig. 2 Correlation of wiggles predicted by frequency analysis with MASCA calibration curve¹² *a*, geological series.

curve. The actual frequencies of the dates, grouped in decades, were then tested against this smoothed curve, using 1%, 5% and 10% probability criteria¹⁰.

It was possible to identify several probable wiggles. Beyond 14,000 yr b.p. the frequency of the dates is too low (Fig. 1) to pick up with certainty anything other than a possible irregularity at about 29,000 yr b.p. This correlates moderately well with the shift in the $^{18}\text{O}/^{16}\text{O}$ ratio reported from the Camp Century ice sheet between 30,000 and 35,000 yr BP¹¹. Excluding irregularities which extend over just a single decade, only five wiggles are significant at the 1% level: they occur in two major groups at about 3,800, 4,400 and 4,700 yr and 8,800 and 8,900 yr b.p. The archaeological data, at a low significance level, indicate two wiggles, at 200 and 400 yr b.p., which may be assigned to the original Suess and de Vries deviations. There is quite a good correlation between the irregularities predicted by this study and the small scale variations (which are nevertheless important for archaeological dating) in the recently published MASCA dendrochronological calibration curve (Fig. 2). The chief difference is the almost complete absence of wiggles in the third millennium BC.

There is also a remarkably good correlation between the irregularities found in this study and Bray's¹³ estimates of the dates of maximum glacial retreat (we assume that his dates are uncorrected radiocarbon years). It is therefore likely that the most intense and long lasting wiggles predicted by us—at about 8,600–9,000 yr b.p.—correspond to the large climatic change at the beginning of the present interglacial. This could be used to try to obtain an absolute dating for this irregularity. If the slope of the dendrochronological calibration curves from 1,000 to 5,000 yr BP were to continue back indefinitely, the period 8,600 to 9,000 yr b.p. (radiocarbon) would correct to 10,500–11,000 yr BP. There is some difficulty in obtaining estimates of climatic events which do not depend on uncorrected radiocarbon dating. The oxygen isotope profiles published by Johnsen *et al.*¹¹ show that the Allerød change was completed by about 11,000 yr BP in the Greenland ice core, which fits rather well with our extrapolated correction. On the other hand, Stuiver's curve relating the age determined by the ^{14}C method to varve counts⁷, shows a large deviation in both Swedish and Minnesota varves at about 8,000–8,500 yr BP. If these are sidereal dates, identical with the irregularity under discussion, the dendrochronological correction would be zero at about this time. On this graph, however, the Swedish varves show absolutely no shift in $\Delta^{14}\text{C}$ over the period from 8,500 to 12,500 yr BP (ref. 14), which does not seem to correlate with the $^{18}\text{O}/^{16}\text{O}$ record at

* Irregularity at 3,770 – 3,810 yr b.p. in combined data ($P < 0.01$).

† Irregularity at 6,910 – 7,020 b.p. in archaeological data ($P < 0.05$).

all. Moreover, this interpretation of the Swedish data has been disputed¹⁵. At present, we prefer to correlate our chart of irregularities with the oxygen isotope profile, partly because of the coincidence at 30,000 yr BP and (with the Southern Hemisphere profile) at 4,000 yr BP, and partly because a massive ^{14}C correction factor would explain the present dearth of dates for the Mesolithic in the period 8,000 to 10,000 yr BP (J. B. Campbell, personal communication). This identification is very tentative.

Nonparametric search techniques require a point estimate for each event that forms part of the frequency, whereas radiocarbon determinations, by their nature, include a statistical uncertainty. We are aware that in converting from one to the other we have lost the information contained in the estimate of standard deviation accompanying each published date, but it was inevitable that many different kinds of sample, with different inherent errors, should be brought together, if enough dates were to be assembled to cover adequately a long time-span. No single laboratory could have provided enough dates for this purpose. We feel that our approach was justified in that, up to about 7,000 yr b.p. (after which archaeological dates become very infrequent), there is substantial agreement between the dates of wiggles predicted by the geological and archaeological dates taken separately, particularly in the period of intense disturbance from 4,000 to 5,000 yr b.p. It is likely that some smaller wiggles may have become blurred, but in any case we do not think that the method described here would pick up the recently reported decadal rhythms. We wished in the first instance to see whether independent evidence could be provided for any of the fluctuations of about a century's duration, which characterise the Suess curve. For a similar reason we included dates from both the Old World and the New World, and from both hemispheres. There has been an increasing tendency for archaeologists to point out that the dendrochronological evidence for ^{14}C calibration is at present derived from a relatively small area of the United States, and to draw attention to apparent discrepancies in certain millennia and in certain areas

of the Old World (for example, the Mediterranean basin). It therefore seemed important to establish 'global' wiggles, although it would undoubtedly be interesting in later studies to test separately dates from all quadrants of the earth.

We are satisfied that there are about four serious wiggles in the dendrochronological calibration curve, concentrated in the second and third millennia BC. It should not be difficult to determine the shapes of the irregularities by standard statistical techniques, now that the regions in which to search have been identified.

We would like to thank Dr H. E. Suess for discussion on this topic.

Polymer structures and turbulent shear stability of drag reducing solutions

THE phenomenon of frictional drag reduction in the turbulent flow of Newtonian fluids, by the addition of high molecular weight polymers, has been known for some time. Because of the great potential it offers in various technological applications this phenomenon has generated considerable engineering interest. Unfortunately, when a limited volume of polymer solution is continuously exposed to mechanical shearing action, either by repeated use¹ or by passing through long pipelines², drag reduction rapidly declines, indicating a rapid breakdown of the polymer molecules³. This polymer degradation greatly limits the application of drag reducing polymers. When considering the use of high molecular weight polymers in operating systems their shear stability must be considered as equally important as their effectiveness in drag reduction. Polymer degradation effect is likely to be caused by the scission of molecular entanglements or the breaking of individual molecules induced by the shear stresses associated with very high local shear rates⁴. But previous studies were made mainly with linear polymers such as polyethylene oxide (PEO) and polyacrylamide (PAM), because a linear structure was believed to be most effective⁵. We have studied the effect of polymer structure on turbulent drag reduction by synthesising drag-reducing agents of different structures⁶. Here we present the results of an investigation of the degradation behaviour of a highly branched

PAM, and compare the results with those observed with ordinary linear polymers.

The branched PAM sample was synthesised by grafting PAM chains on to a small, nucleus molecule. The nucleus was prepared by reacting tetraethylene pentamine with epichlorohydrin. A typical structure of this backbone molecule may be represented as follows:

There was a total of seven potential chain-grafting sites in this molecule. Through the redox reaction of the molecule with ceric ion, the graft polymerisation of acrylamide was initiated on the ROH groups⁷. The polymerisation started instantaneously and proceeded at a much higher rate than with the ceric ion alone. This suggested that the probability of ungrafted acrylamide polymerisation occurring is negligibly small. The polymerisation was carried out in aqueous solution using the redox system under a nitrogen atmosphere for 5 h at 32° C, resulting in a gel-like, transparent material which was completely water-soluble. The intrinsic viscosity of this PAM compound was 6.13 dl g⁻¹, leading to an estimated molecular weight of 1.7×10^6 (using the relationship in ref. 8). But as this relationship was developed for linear PAM, it may not be relevant to the present highly branched structure. The details on the polymerisation will be published elsewhere.

The drag-reducing capability of the branched PAM sample was characterised in a capillary flow system of diameter 0.1575 cm. A detailed description of the apparatus was presented elsewhere⁹. Using the characterisation technique developed

Fig. 1 Degradation behaviour of the 100 p.p.m. solutions of PEO (closed symbols) and branched PAM (open symbols).

earlier¹⁰, the effectiveness of the branched PAM was evaluated at a fixed Reynolds number of 9,000. On a unit concentration basis at infinite dilution this compound had an effectiveness measure (Eff) = 4.14 in units of percentage drag reduction per parts per million (%/p.p.m.). The degradation behaviour of commercial linear PEO and PAM compounds with similar effectiveness was compared with that of the branched PAM. Polyox-WSRN-3000 (Union Carbide Corp.; Eff = 4.15 %/p.p.m.) and Magnifloc 905N (American Cyanamid Co.; Eff = 3.78 %/p.p.m.) were used. The solutions were repeatedly passed through the capillary and the change in percentage drag reduction recorded for each pass. These measurements provided

Fig. 2 Degradation behaviours of the 100 p.p.m. solutions of linear PAM (closed symbols) and branched PAM (open symbols).

a relative measure of the shear stability of these compounds of different molecular structure.

The degradation behaviour of 100 p.p.m. solutions of the branched PAM, the linear PAM and PEO are shown in Figs 1 and 2. The data show comparisons on an equal concentration basis with approximately equal initial percentage drag reduction. At three different Reynolds numbers, the solutions of linear PAM and PEO showed a very rapid decline in percentage drag reduction with increasing number of passes through the capillary. The rate of the decrease in percentage drag reduction is much slower for the branched PAM. Such a contrast in degradation behaviour clearly demonstrates the superior shear stability gained by molecular branching. Physically, this may be explained by the molecular scission concept. Recent experimental results of a degradation study of polyacrylamide in a high shear flow¹¹ showed general agreement with the theoretical prediction of Bueche's midpoint break theory¹². According to this theory, polymer chain breaking does not take place at random along the chain but occurs predominantly in the central portion of the chain where the extending forces are maximum. In the case of a linear polymer, this kind of chain breakage will immediately reduce the polymer molecular weight to approximately one-half. The drag reducing ability of

the compound is therefore greatly reduced because of the strong dependence of drag reduction on polymer molecular weight⁶. In the case of the branched PAM sample, however, the reduction in molecular weight is apparently less drastic probably because the shear forces acting on the polymer are distributed among the individual chains. Any reduction in molecular weight, when it occurs, will probably be of the order of a chain length rather than one-half of the molecule.

It can be seen that the improvement of the shear stability by branching is more pronounced at lower Reynolds numbers. If turbulent drag reduction is considered as a manifestation of the intensive interactions between polymer molecules and the dissipative turbulent eddies, this Reynolds number effect may be explained as follows. In the dissipation range, the Komolgorov eddy scale, η , is related to the kinematic viscosity ν and the dissipation ϵ by $\eta = (\nu^3/\epsilon)^{1/4}$. It can easily be shown that¹³

$$\eta/d \sim (\nu^3 d^3 / u^3)^{1/4} / d = (\nu / u d)^{3/4} = Re^{-3/4}$$

or

$$\eta \sim d / Re^{3/4}$$

where d is the capillary diameter and Re the Reynolds number. Since d is fixed in the present case, the turbulent dissipative eddies have relatively smaller scales at higher Reynolds numbers than those in flows of lower Reynolds numbers. The degraded polymer molecules, presumably having smaller coil sizes, may still be able to interact effectively with the dissipative eddies in flows of higher Reynolds numbers, but have become less effective in lower Reynolds number flows.

The present results also suggest that the linear PAM solution shows as poor shear stability as the PEO solution. This is in contrast to the general belief that the PAM solution is more shear stable than the PEO solution in turbulent flows. From the chemical point of view, a better shear stability for PAM can be possible only if some turbulence-induced oxidation is involved in the degradation process, as proposed by White¹⁴, but this is not obvious according to the present data. We showed that the presence of counter-ions surrounding the domain of an ionic polymer could greatly improve the polymer shear stability in turbulent flow¹⁵. Most of the previous PAM degradation studies used commercially manufactured compounds. These materials, after long handling and storage periods, could very possibly have become partially hydrolysed to form copolymers of PAM and polyacrylic acid. This is especially true if the materials were exposed to moisture for a long time. This variation, as we have shown¹⁵, could very well introduce higher resistance to mechanical shearing to these so-called PAM compounds.

Hardening of immersed metals by ultrasound

DURING electrodeposition in an ultrasonically agitated solution, the hardness of copper anodes increases, and sometimes they perforate in a nonuniform manner¹. Deposits plated from electrolytes which have been subjected to ultrasound have a higher hardness than those produced from still solutions^{2,3}. Here we report on the change in hardness of a wide range of metals.

We used strips of metal about 10 cm long, 1 cm wide and 0.1 cm thick. The majority of these were annealed for 2 h at a temperature of about 60% of the melting point (in degrees absolute) and the hardness (HV) was measured with a microhardness tester using a load of 25, 50 or 100 g. The same load was used in all the measurements of any one metal.

The metal strips were subjected to ultrasound by immersing them in tap water in an ultrasonic tank. The specimens were treated individually to prevent shielding and were clamped centrally and perpendicularly about 1 cm above a 12.5 cm diameter transducer probe. The ultrasonic field, of frequency 13 kHz and intensity 930 W m⁻², was applied for 5 min. The specimens were then removed and the hardness of an area in the centre of the strip was measured immediately. This procedure was repeated keeping the metals in the ultrasonic field for increasing intervals of up to a maximum of 1,500 min. Tin and zinc, however, perforated before the end of this time. The hardness was measured again one month after the completion of the experiment to check whether any change had occurred during storage at room temperature.

The changes in the hardness of the various metals during the time of ultrasonic bombardment are shown in Fig. 1 and the relevant data are given in Table 1.

Fig. 1 The effect of ultrasonic agitation on the hardness of immersed metals. Metals with the same crystallographic structure are grouped together wherever possible: a, Mg; b, Zn; c, Cd; d, Sn; e, mild steel; f, Ni; g, brass; h, Cu; i, Nb; j, Al; k, Zr; l, Ti; m, Ta.

Table 1 Changes in hardness of immersed metals produced by ultrasound and during subsequent storage

Metal	Crystal structure	Hardness HV			Hardness changes (%)		Storage temperature (K) Melting point (K)

Tin	Tetragonal	11.8*	16.0§		+ 36		

f.c.c., face-centred cubic; b.c.c., body-centred cubic; c.p.h., close-packed hexagonal. Microhardness load: *25 g; †50 g; ‡100 g. §After 360 min.

The increase in hardness produced by ultrasound was not uniform but varied considerably over the surface; this was particularly noticeable on some metals which perforated during bombardment. Variations were also observed when the microhardness was measured at different areas on the surface, and because of this the readings were always taken on the same central area of the specimen. These variations may result from the presence of a standing wave which would form nodes and antinodes in the water above the probe.

The hardness of all the metals except tin, which showed only a slight change, increased rapidly at first and then tended to reach a steady value; a further increase in hardness was usually observed over the period of bombardment 360–1,500 min (Fig. 1).

There are certain similarities in the patterns of the percentage increase in hardness of metals which have the same crystallographic structure (Fig. 1). Face-centred cubic metals increased by about 80–150%, whereas body-centred cubic metals showed a much lower change of 27–77% and the change in close-packed hexagonal metals ranged from 27–130%. Tantalum, which is much purer than niobium showed less resistance to dislocation movement and underwent a higher increase in the percentage hardness. The lattice of brass was more strained than that of copper, which resulted in a much lower increase.

The increase in hardness of a metal exposed to ultrasound may result from the cavitation that occurs at the metal surface. The pressure in cavitation bubbles before they collapse has been calculated to be several thousand atmospheres⁴ and, as the cavities implode, shock waves deform and harden the surface. Thus the lattice of the material at the surface of the metal may be distorted, and internal strains may be present in the surface layers.

A very significant decrease in the hardness during storage was observed with many of the metals, and in some cases, such as Ti, the value dropped to almost the initial reading. This softening process is too high to be a result of annealing at room temperature but could be caused by recovery at room temperature. There is a definite trend in metals with the same crystal structure (Table 1) between the percentage decrease and the ratio of storage temperature to melting point. Greater percentage decreases occur with the higher ratios which suggests that it is the recovery of point defects which gives the observed softening.

We thank the Science Research Council for financial

support (C. T. W.), and Mr A. Grange of Ultrasonics Ltd, and Professor Waldron.

Anion coordination geometry as a determining factor in crystallographic shear

ATTENTION has been drawn to some of the consequences of anion polarisation in one crystallographic shear (CS) system, the reduced titanium oxides¹; particularly to the effect on crystal energy and cation coordination geometry. The existence of polarisation in typical CS structures is indicated by the values of certain common properties—the dielectric constant and refractive index are both high—by the more direct, experimental determination of net ion charges in some double CS (column, or so-called 'block') structures², and by the characteristic persistence of the cation coordination geometry³, which is invariably octahedral.

Polarisation produces some directed covalency. The implications of this for anion coordination geometry are immediate and simple, but far reaching. For a second row element of the periodic classification, such as oxygen, the maximum coordination number for covalent bonding is $CN(O) = 4$. Thus, in ordered, reduced-rutile structures there can be only one set of CS planes: this raises the coordination number of anions at the CS planes from $CN(O) = 3$ in the rutile parent, to the maximum $CN(O) = 4$. On the other hand, when an ReO_3 -type structure is reduced by CS, $CN(O)$ is increased from 2 to 3 for one set of CS planes (slab structures). A second, intersecting set of CS

planes is possible before the maximum $CN(O) = 4$ is attained, thus producing column structures. True block structures—with three intersecting sets of CS planes—could not exist, because $CN(O) = 5$ would be produced (as it would in column structures derived from a rutile type parent).

Because $CN(O) \leq 4$, the minimum stoichiometry for any CS structure MO_x will be $x_{min} = 1.0, 1.5, 2.0$ for cation coordination numbers $CN(M) = 4, 6, 8$, respectively. (This considers only the $CN(M)$ values appropriate to the common regular cation coordination polyhedra: tetrahedron, octahedron and cube.) The stoichiometry of the parent structure must be $x > x_{min}$. Therefore, for octahedrally coordinated cations, the most reduced CS derivative will have $x = x_{min} = 1.5$ (compare with corundum type M_2O_3). On the other hand, CS in reduced fluorite type oxides is immediately ruled out, even though their bonding is of a covalent character⁴; because already, in the parent structure, $CN(O) = 4$, and $x = x_{min} = 2.0$.

These deductions are all in complete accord with a vast amount of experimental evidence. Furthermore, the 'distortions' from conventionally idealised structures (with regular $[MO_6]$ octahedra) to the real structures, which occur in the parents and in CS, column and bronze type derivatives, clearly show the strong tendency towards anion coordination symmetries appropriate to sp, sp^2 and sp^3 hybridisation, and characteristic of $CN(O) = 2, 3$ and 4 .

For tetrahedrally coordinated cations the situation is unclear: no transition metal oxide is known to retain exclusively $CN(M) = 4$ on reduction. For example, although CrO_3 contains only $[CrO_4]$ tetrahedral groups, the (high pressure) structure of Cr_6O_{15} contains $[CrO_6]$ octahedra in addition to $[CrO_4]$ tetrahedra, whereas the (ambient pressure) structures of the reduced β and γ oxides are unknown⁵.

In other metal oxide systems either the cations are not of variable valency (which is essential for CS in a binary system) or the situation is complicated by the effects of stereochemically active lone pairs of electrons (Ge, Sn, Pb, Sb, Bi)⁶. Perhaps they have been insufficiently studied. That is certainly true of systems with other anions, such as fluoride. There, however, polarisation effects will be much smaller than with the oxide ion, and there is certainly no evidence so far of CS in metal fluorides, although it does occur in oxide fluorides.

Molecular mechanism for missense suppression in *E. coli*

THE missense mutation *trpA36* results in a Gly (GGA) → Arg (AGA) amino acid substitution at position 211 of the tryptophan synthetase A protein¹. Suppressors of *trpA36* have been derived by mutation in *glyT*, the gene specifying tRNA^{Gly 2}_{GGA/GG}, and in *glyU*, which specifies tRNA^{Gly 1}_{GGG} (refs 2–4). Transfer RNA from strains carrying either of the *glyTsuA36* or *glyUsuA36* alleles inserts glycine into polypeptides, *in vitro*

and *in vivo*, in response to the arginine codon, AGA^{3,5,6}. We report here a comparison of the nucleotide sequences of tRNA^{Gly 2}_{GGA/GG} and tRNA^{Gly 2}_{suA36(HA)}; the *glyTsuA36(HA)* mutation results in a C → U base change at the 3'-end of the anticodon of tRNA^{Gly 2}_{GGA/GG}, which causes a subsequent, enzyme-catalysed modification of the A directly adjacent to the 3'-end of the anticodon.

³²P-labelled tRNA^{Gly 2}_{GGA/GG}, obtained from *glyT*⁺ *E. coli* strains, was purified by the methods of Gillam *et al.*^{7,8}. ³²P-labelled tRNA^{Gly 2}_{suA36(HA)} was obtained by infection of strain BF266 with the phage, λ h80d*glyTsuA36*, (ref. 9) and was purified by BD-cellulose⁷ and RPC-5 reverse phase chromatography¹⁰. The tRNAs were sequenced by the methods of Sanger and co-workers, as described by Barrell¹¹. A complete account of the purifications and sequence procedures will be presented elsewhere.

Ribonuclease T₁ fingerprints of the two tRNA species are quite similar, differing only in the position, and sequence, of oligonucleotide T-13 (Fig. 1), which forms the anticodon loop of the tRNA molecule (Fig. 2). Oligo T-13, from tRNA^{Gly 2}_{GGA/GG}, has the sequence CCUCCAAG; oligo T-13', from tRNA^{Gly 2}_{suA36(HA)}, has the sequence CCUUCU^UAAG. A portion of both species has an unidentified modified U in the wobble position of the anticodon (Fig. 2). The *glyTsuA36(HA)* mutation, therefore, replaces the C in the third position (3'-

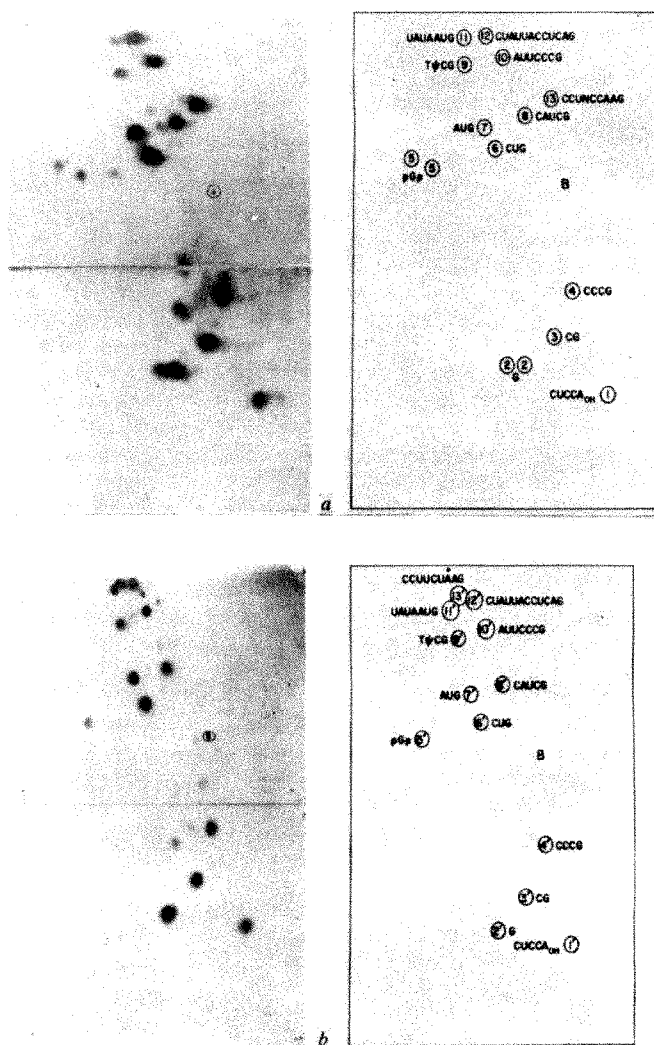

Fig. 1 A comparison of ribonuclease T₁ fingerprints of: (a) tRNA^{Gly 2}_{GGA/GG}; (b) tRNA^{Gly 2}_{suA36(HA)}. First dimension electrophoresis on cellulose acetate at pH 3.5 was from right to left. Second dimension electrophoresis on DEAE paper in 7% formic acid was from top to bottom. The symbol B denotes the position of the blue dye marker (xylene cyanole FF).

Fig. 2 tRNA^{Gly 2}_{GGA/G} drawn in the cloverleaf configuration. The arrows indicate the changes resulting from the *glyTsuA36* (HA) mutation. N, an unidentified derivative of U, is present in a portion of both species. A*, as yet unidentified, is apparently a derivative of N⁶-carbamoylthreonyl-A.

end) of the anticodon of tRNA^{Gly 2}_{GGA/G} with a U, changing the anticodon sequence from UCC to UCU. The observed anticodon sequences are, as might be expected, complementary to the codons recognised by the tRNA species *in vitro* and *in vivo*.

Other missense suppressors can arise by alteration of the anticodons of, and thus the codons recognised by, particular tRNA species. For example, tRNA^{Gly 3}_{suA78}, which inserts glycine into polypeptides in response to the cysteine codons, UGU and UGC, was derived from tRNA^{Gly 3}_{GGU/C} by a C→A base change at the 3'-end of the anticodon¹². tRNA^{Gly 3}_{ins}, which recognises the glycine codons GGA and GGG, was derived from tRNA^{Gly 3}_{GGU/C} by a G→U base change in the wobble position of the anticodon¹³. tRNA^{Gly 1}_{suT}, which recognises the glutamic acid codon, GAG, was derived by a C→U base change in the middle position of the anticodon of tRNA^{Gly 1}_{GGU} (ref. 14). In all cases, the anticodons of the suppressor tRNAs are complementary to the missense codons suppressed by these tRNAs.

As shown in Figs 2 and 3, the A adjacent to the anticodon of tRNA^{Gly 2}_{suA36(HA)} is modified, while the corresponding A in tRNA^{Gly 2}_{GGA/G} is not. The modified nucleotide, as yet unidentified, is converted to Ap by treatment with alkali; it exhibits an electrophoretic mobility at pH 3.5 (relative to Up) of 0.98, and chromatographic mobilities in systems A and B (ref. 11) (relative to Up) of 0.66 and 0.5 respectively. Since derivatives of N-[9-(β-D-ribofuranosyl)-purin-6-ylcarbamoyl]threonine (t⁶A) are found adjacent to the anticodons of tRNA species recognising codons beginning with A (ref. 15), we suggest that the modified A adjacent to the anticodon of tRNA^{Gly 2}_{suA36(HA)} might be such a derivative. The enzymes responsible for this modification must recognise, at least in part, the anticodon sequences of prospective tRNA substrates. An analogous

situation exists with tRNA^{Gly 3}_{suA78}, which has 2-thiomethyl-6-isopentenyl-adenine (ms²i⁶A) adjacent to the anticodon; the corresponding A in tRNA^{Gly 3}_{GGU/C} is not modified (Fig. 3)¹². Some suggestions have been made concerning the physiological significance of such modifications; for example, tRNA^{Tyr}_{su111} lacking the isopentenyl modification adjacent to the anticodon shows a greatly reduced ability to recognise the codon, UAG, *in vitro*, but appears to function normally in other respects¹⁶.

The following observation suggests that the greatly reduced rate of aminoacylation of tRNA^{Gly 2}_{suA36(HA)} (10⁻⁴ times that of tRNA^{Gly 2}_{GGA/G} under identical conditions)^{2,3,17} is a result of the base change in the anticodon, rather than the modification of the adjacent A. A tRNA capable of inserting glycine into polypeptides, *in vitro*, in response to the arginine codon, AGA, has been derived from tRNA^{Gly 2}_{GGA/G} by nitrous acid deamination, presumably of the C at the 3'-end of the anticodon. This altered tRNA^{Gly 2}, chromatographically different from tRNA^{Gly 2}_{suA36(HA)} and probably lacking modification of the A adjacent to the anticodon, exhibits a greatly reduced rate of aminoacylation¹⁷. The role of the anticodon sequence in the aminoacylation reaction has been suggested for other tRNA species. If the anticodon of tRNA^{Tyr}_{UGG} is changed from CCA to CUA, the altered tRNA can be enzymatically aminoacylated with glutamine¹⁸. If a C in the anticodon of tRNA^{Met} or tRNA^{Val} is chemically modified to U, the tRNA can no longer be enzymatically aminoacylated^{19,20}. Preliminary attempts to isolate unmodified tRNA^{Gly 2}_{suA36(HA)}, in order to test this hypothesis directly, have been unsuccessful; in fact, modification of the A adjacent to the anticodon has been found in the uncleaved precursor of tRNA^{Gly 2}_{suA36(HA)} (S. Chang, and J. C., unpublished results).

Fig. 3 A comparison of the anticodon changes and resulting modification changes of: (a) tRNA^{Gly 2}_{GGA/G} → tRNA^{Gly 2}_{suA36(HA)}, and (b) tRNA^{Gly 3}_{GGU/C} → tRNA^{Gly 3}_{suA78}. In each case, substitution of the base at the 3'-end of the anticodon results in a modification of the adjacent A.

GlyTsuA36 mutations cause pleiotropic effects, of varying severity, on the cell; these effects are due, at least in part, to the loss of GGA translating ability, since they are reversed by the presence of *glyT*⁺ (normal tRNA^{Gly 2}_{GGA/G}) or *glyVins* (tRNA^{Gly 3}_{GGU/C} → tRNA^{Gly 3}_{GGA/G}) (refs 2, 4 and 13). For example, the *glyTsuA36*(HA) allele is semilethal when haploid⁴. The *glyTsuA36*(159) allele, which is probably the result of two or more closely linked mutational events, renders the cell tryptone-sensitive; when shifted from minimal to complex medium, cells carrying the *glyTsuA36*(159) allele cease normal cell division, form long aseptate filaments, and die^{2,21}. Nucleotide sequence studies of tRNA^{Gly 2}_{suA36(159)} may suggest a molecular basis for the less severe pleiotropic effects of *glyTsuA36*(159); *glyTsuA36*(159) may specify a tRNA^{Gly 2} with the *glyTsuA36*(HA) anticodon alteration plus a second nucleotide substitution which allows the tRNA to recognise with low efficiency

the glycine codon, GGA, in addition to the arginine codons AGA and AGG (ref. 4).

X-ray diffraction studies of DNA at reduced water contents

REDUCED water contents probably stimulate most closely the local environment about DNA when it is complexed with protein. At low water contents, less than about six water molecules per nucleotide, the equilibrium conformation for pure DNA is the A form^{1,2}. The A form does not alter with base composition³ whereas the B states of DNA are strongly correlated with chemical composition⁴. The A conformation (A state) is the only one which can be called a distinct form. There are many B type conformations all having ten base pairs per turn. 'C form' is a misnomer. We use the term 'C state' or type for structures having a pitch between 29 and 33 Å and a diffraction intensity distribution of weak, strong, then weak on the first three layer lines.

Since the discovery of the A form¹, all experiments on A-DNA where lattice formation could be detected, have shown the presence of a crystalline state. We have specifically looked for noncrystalline A-DNA but have not found it. In fibres, one might argue that orientation would favour and highlight crystalline regions, but this would not be

the case for unoriented gels. We have dried wet gels to about 70% DNA concentration and subsequent X-ray scattering experiments have shown only B or crystalline A patterns.

As it has been reported that the circular dichroism and Raman spectra of DNA in 80% ethanol is the same as A-DNA in films and fibres^{5,6}, we decided to study the conformation of DNA in this solvent.

Indeed, we found that DNA did adopt the A conformation in 80% ethanol and that this A state was always crystalline and quite similar to that previously observed in gels and fibres (see Fig. 1). We also found that, after the addition of ethanol to a DNA gel, complete formation of the A state could require up to several hours and that, upon the B to A transition, spontaneous preferential orientation sometimes occurred.

In the nucleus, conditions for DNA crystallisation are obviously very unfavourable because of the protein-DNA and water-DNA linkages which are stronger than DNA-DNA interactions. Consequently, it is of biological interest to examine the dehydration of DNA under conditions where A transitions are inhibited.

At high water contents in solution and in fibres DNA assumes conformations of the B type^{2,7} and when a B-DNA gel or fibre is slowly dried at lower relative humidity (r.h.), a transition to the A form is nearly always observed. But, if a hydrated fibre is maintained under tension while it is dried rapidly, the 30% contraction in length required for a B to A transition is inhibited and other conformations are adopted. When a wet gel of *Clostridium perfringens* DNA (69% A-T) is maintained under tension while drying at 20°-25° C, subsequent X-ray fibre patterns show diffraction of the P type at NaCl contents less than 2% and of the

Fig. 1 A pattern of calf thymus DNA in 80% ethanol taken with a torroidal camera in air in a glass capillary tube. The concentration of DNA was about 5%, but it was present as a precipitate. The diffraction is that of the crystalline A state and preferential orientation was observed perpendicular to the length of the capillary. The ring at 3.14 Å is from silicon powder on the capillary. Similar A patterns have been observed with *Cl. perfringens* DNA in 80% ethanol.

Fig. 2 A crystalline B pattern from *Cl. perfringens* DNA at 44% r.h. showing a small amount of A form (notice the slight splitting of the second layer line). The fibre contained 5% excess salt was dried on a fixed platinum support at 37° C.

T type at higher salt concentrations. (The nature of these patterns has been described previously⁸; in short both the T and P structures are more highly wound and have smaller radii than the A, B or C structures.) The P and T states are stable for at least several days at 66% r.h. even if the fibre is freely suspended. But if the r.h. is raised to 98% and then returned slowly to 66% r.h., an A diagram appears. (Similar hysteresis effects have also been observed by Dr. A. M. Levelut at the Laboratoire de Physique des Solides, Orsay.)

If a gel of *Cl. perfringens* DNA on a fixed support is quickly dehydrated by drying at 37° C at r.h. < 66%, a B state is often obtained. These X-ray patterns are more crystalline than any other sodium B patterns yet observed. Some patterns (as in Fig. 2), however, show the presence of small amounts of A-DNA implying the existence of a metastable mixture. This low humidity B state is stable for at least 2 d at 44% r.h. The lithium salt of his DNA gives a crystalline B pattern at lower r.h. (ref. 8) but no C pattern has been observed with the lithium salt. Experiments with the magnesium salt of *Cl. perfringens* DNA (Mg-DNA) give a pattern at lower humidities which resembles those of C states in the intensity distribution on the lower layer lines but in which the ninth layer line, which has been related to a slight base tilting, is much weaker than in the C patterns. Thus *Cl. perfringens* DNA can adopt at least five different forms at the same water content.

It was accidentally observed that the sodium salt of calf thymus DNA (Na-DNA) gave a C pattern (S.B. and P. Tougard, unpublished) which was almost identical to the published lithium salt C diagrams (see Fig. 3). Subsequent experiments with a variety of pulling conditions and salt contents failed to give C patterns. It was then found, however, that calf thymus DNA dried at 37° C (between 30 and 66% r.h.) usually gives a C pattern. This state is metastable at 66% r.h. and 'decays' into the A form after about a day. An immediate C to A transition occurs at lower r.h. if a C-DNA fibre is cut loose at one end from its support. This rapid transformation is accompanied by a 30% contraction in fibre length. Calf thymus DNA can also give very crystalline B patterns at 30-66% r.h. when dried at 37° C. For calf thymus DNA, it seems that high salt conditions favour the metastable B state, whereas at salt contents less than about 3%, C structures seem to predominate.

Stable states are produced by several agents which are

known to block the B to A transitions. The result is that at lower humidity new conformations are adopted, all of which are more highly wound than the A state. One agent known to block B to A transition is the lithium ion. The A form has never been observed with calf thymus Li-DNA (nor with *Micrococcus luteus* or *Cl. perfringens* DNA in this laboratory). Instead a C state is found at lower r.h. (ref. 10). Calf thymus Mg-DNA also does not exist in the A form but instead adopts a C configuration at lower r.h. (ref. 11); and in mixtures of sodium and magnesium salts, the relative amount of A-DNA we observed was far less than the $\text{Na}^+/\text{Mg}^{2+}$ ratio. When glucose residues are present, as in phage T2 DNA, or with nonintercalating acridine orange or proflavin, instead of the A form a structure having eight or nine base pairs per turn exists at r.h. less than 80% (refs 12, 13). In fact, the fibre patterns shown by T2 DNA at low r.h. (ref. 12) are very similar to those of our P form. In chromatin the A form has never been detected and experiments in this laboratory show that small amounts of histone protein also inhibit the B to A transition in fibres. Thus, even if the requirement for crystallinity were not sufficient to prevent an A transition *in vivo*, these blocking agents, some of which are quite common in the cell, would strongly inhibit it.

Fig. 3 A sodium C pattern from calf thymus DNA at 44% r.h. having a layer line separation of 31 Å. The fibre was dried on a fixed support at 37° C and over 44% r.h.

On the other hand, A-DNA, the only state which is invariant with base composition, might provide the best substrate for both RNA and DNA polymerases. Yet our results strongly imply that the A form of DNA can exist *in vivo* only when hybridised with RNA, for here DNA is forced to adopt the A configuration¹⁴. It may be that RNA or ribonucleotides play the role of a catalyst in transcription and replication by driving DNA to the A-state.

We thank Dr F. H. C. Crick for his helpful comments on the manuscript. This work was supported by grants from CNRS and DGRST.

RNA synthesis specific for an integrated adenovirus genome during the cell cycle

WHEN adenovirus transforms a cultured mammalian cell, substantial portions of the viral genome can be integrated into the host cell chromosomes and at least a fraction of this integrated genome is transcribed¹. Approximately 50% of the early sequences observed in the lytic infections are synthesised in the transformed cell². In randomly growing transformed rat embryo cells, the virus transcripts in the nucleus are in the large molecular weight, heterogeneous RNA covalently linked to cellular RNA³. These transcripts are apparently processed before they appear on cytoplasmic polyribosomes³. To date, there has been little evidence concerning the synthesis and post-transcriptional modifications of viral transcripts during the cell cycle in the transformed cells. The first question to be asked is, is there continuous synthesis of viral transcripts from at least some portion of the integrated genome, or is synthesis limited to one phase of the cell cycle? We have investigated this question in synchronised rat embryo cells transformed with adenovirus type 2 (Ad2-T)⁴. The synthesis of viral RNA transcripts was correlated with the life cycle of the cell which can be defined as consisting of a period of DNA synthesis (S phase) followed by a period of growth before mitosis (G₂), mitosis (M), and another growth period following division prior to DNA synthesis (G₁). Our data indicate that virus-specific RNA was transcribed throughout the cell cycle along with cellular RNA synthesis. Viral RNA transcription was restricted during mitosis coincident with the restriction of cellular RNA synthesis.

All experiments were performed with a cloned population⁵ which demonstrated levels of T antigen and synthesis of virus-specific RNA at least equivalent to those of the uncloned population. Cells were maintained in spinner cultures in Eagle's MEM (without calcium)⁶ enriched with 5% dialysed calf serum and 1% foetal bovine serum.

Cultures were synchronised in S phase by exposure to thymidine. Incorporation of ¹⁴C-thymidine into acid-precipitable material began immediately after release from a double thymidine blockade (Fig. 1). Incorporation reached a maximum at about 3 h and then declined during the 4–6 h after synchronisation. Autoradiography revealed that 85% of the cells were synthesising DNA during the period 1–5 h following resuspension as opposed to 22% at 7–11 h. Approximately 90% of the culture passed through mitosis during a 4 h interval beginning at about 6 h after synchronisation. If the cells were released in the presence of colcemid, between 60 to 70% of cells accumulated in metaphase by about 10 h and an additional 20 to 30% seemed to be arrested in prophase.

Synthesis of cellular and viral RNA was compared in a

Fig. 1 Synchronisation of Ad2-T cells following thymidine blockade. A suspension culture of Ad2-T was synchronised with 2.5 mM thymidine by incubating the cells for 15 h in the presence of thymidine, resuspending in fresh medium for 9 h followed by an additional 14 h exposure to thymidine. At the indicated times after blockade 2 ml aliquots (approximately 10⁶ cells) were transferred to tubes containing 0.5 μ Ci ¹⁴C-thymidine (specific activity 40–60 mCi mmol⁻¹, New England Nuclear, Boston, Massachusetts). After incubation for 20 min at 37° C, the acid-insoluble radioactivity was determined as previously described⁷. Data were normalised to c.p.m. per 10⁶ cells. At the time of resuspension an equal amount of the culture was treated with colcemid (0.025 μ g ml⁻¹) and the accumulation in metaphase scored. If apparent prophase cells were counted along with metaphase cells, the final proportion of cells not in interphase was generally 85–90%. Cell concentration was determined with a haemocytometer and the mitotic index was determined with phase microscopy. ●, ¹⁴C-thymidine; ▲, cells ml⁻¹; Δ, % metaphase.

population of cells progressing from S phase, through G₂ and into metaphase (Fig. 2). Aliquots of cells were exposed to ³H-uridine for 1 h intervals during this period. RNA was prepared from whole cells⁸ and analysed for total radioactive incorporation and for incorporation into virus-specific material using the low temperature DNA-RNA hybridisation procedure in the presence of 7.5 M urea⁹. Figure 2a illustrates that viral RNA synthesis corresponds to total cellular RNA synthesis. Incorporation of uridine into both viral and cellular RNA increased following release from thymidine, reached a maximum in S and steadily declined as the population proceeded through G₂ into metaphase-arrest.

The extent of restriction of viral RNA synthesis during mitosis was determined using metaphase-arrested cells collected from albumin density gradients as described in the legend of Table 1. Interphase cells, subjected to the same manipulative procedures, were added to the metaphase cells to form populations of defined content. These mixtures were incubated at 37° C with ³H-uridine for 1 h and the total cellular RNA was prepared as described (Fig. 2). Incorporation into virus-specific RNA decreased linearly with increasing proportion of metaphase cells and approached zero. This decrease paralleled that of total cellular RNA synthesis suggesting that synthesis of both species is restricted to the same extent during metaphase.

Since the G₂ period is short and is not clearly defined following thymidine synchronisation (Fig. 1), it could be argued that viral RNA was synthesised primarily during S and that restriction during G₂ was masked by the entry of cells into mitosis. The nearly complete restriction of viral RNA synthesis during metaphase made a more precise examination of the G₂ phase possible. A culture was synchronised with thymidine, and colcemid was added at the time of release from the second blockade (Table 1). The culture was divided into three aliquots which were continuously exposed to ³H-uridine for 6, 4, and 2 h before

Differentiation

Differentiation, published bi-monthly, provides the opportunity for interdisciplinary communication. This journal offers up to date information and synthetic views of a problem underlining the whole biological phenomenon – differentiation. It aims to cover the following areas of study: embryonic differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions in vivo and in vitro, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Recent papers include:

Degree of differentiation in non-proliferating cells of mammary carcinoma, C. V. Wylie, P. K. Nakane and G. B. Pierce. **DNA synthesis and the production of antibodies by lymphoid tissues**, G. Harris. **The principle of sequential dependence in cellular differentiation**, P. A. Riley. Edited by: Dimitri Viza. Faculté de Médecine Pitié Salpêtrière, Paris.

Fluorescence techniques have undoubtedly become one of the most important research tools in biochemistry as well as in cell biology. This volume includes some 40 papers on quantitative fluorescence techniques contributed by chemists, biochemists and cell biologists to a conference, the main aim of which was to encourage a fruitful interaction based on a common methodology between biochemists and cell biologists or cytochemists. Such interaction is essential if we are to elucidate the composition, activity, and organization of the cell at the molecular level. The papers in this volume clearly illustrate the complementarity between data obtained by fluorometric techniques, as applied mainly to solutions, and the information derived from microscope fluorometry in correlation to the single cell and its structure.

Contents: Opening Remarks. — Introductory Papers. — Instrumentation and Standardization in Fluorometry and Microscope Fluorometry. — Cytofluorometric Determination of Cellular Substances. — Investigation of Enzyme Reactions and Transport Mechanisms. — Fluorescent Molecular Probes for Complex Biological Molecules. — List of Attendees. — Subject Index.

Brandenburg are changing the face of nuclear engineering...

TAKE A LONG LOOK AT THIS BIN.

All these NIM modules come from Brandenburg.

The N20, for example, is revolutionary since within its slim case is a facility to interface with radiation detectors, pulse counters and pulse analysis equipment. Put simply, there's more technology and more freedom in much less space than you've been used to. And with fewer front panel controls.

The other modules are similarly advanced.

Now the price.

Our NIMs cost – on a pound per function basis – much less than other comparable equipment. Simply because we spent years in R and D updating manufacturing

techniques. We've simplified the intermodule electrical connections and minimised power consumption, too.

We've also got in production four more series of modules which will be released in coming months. (They include a scaler, a scaler timer, print controllers and much, much more.)

We invite you to ask us for our comprehensive data. We'll then automatically keep you in touch with each of our new modules as they are produced.

We'll also tell you about the Brandenburg NIM Bin and our series of multi-channel analysers. All in all, Brandenburg (an entirely British company) are now bringing you comprehensive nuclear engineering from our new division – which is backed by over twenty years of high technology engineering.

Brandenburg Limited,
Nuclear Engineering Division, 939 London Road,
Thornton Heath, Surrey, CR4 6JE, England.

collection of metaphase cells. The advantage of this approach is that by isolating metaphase cells, the incorporation during a given labelling period represents synthesis for a maximum of that time before mitosis. For example, cells incorporating radioactivity in the 2 h interval immediately preceding the collection of metaphase-arrested cells should represent synthesis by a fairly homogeneous population of cells in G_2 . As expected metaphase cells collected from the population exposed to radioactivity for 6 and 4 h contained significant amounts of labelled virus-specific RNA. A lower level of incorporation was found in the third population labelled for 2 h. This latter result clearly indicates synthesis of viral RNA during G_2 .

Between 6 and 10 h after thymidine synchronisation, the population of cells passed from G_2 through mitosis into G_1 (Fig. 1). No evidence of DNA synthesis was observed in this population until 9 h later. Aliquots of cells were exposed to 3H -uridine for 1 h intervals beginning 8 h after synchronisation in S phase and RNA was prepared as previously described (Fig. 2b). There was minimal incorporation of uridine into both cellular and viral RNA coincident with the time of mitosis. Incorporation then rose to fairly constant levels as the population progressed into G_1 . Viral RNA synthesis seems to follow the resumption of cellular synthesis following mitosis. There is a steady decay in synchrony as the population progresses from S phase to G_1 . The following techniques to initiate synchrony in G_1 were surveyed but proved unsuccessful: selective detachment of mitotic cells¹⁰, release from density growth inhibition¹¹, serum deprivation¹², and isoleucine deletion¹³.

We conclude that at least some virus-specific RNA was synthesised at all times during the cell cycle except mitosis.

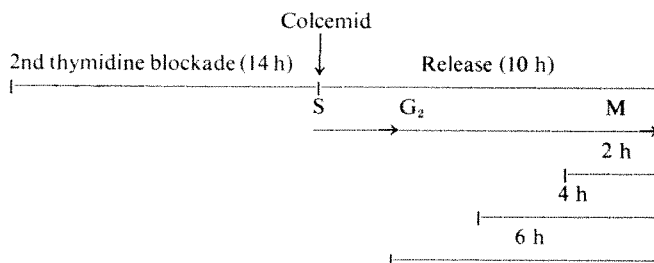

Fig. 2 Cellular and viral RNA synthesis following thymidine blockade. Ad2-T cells were used directly as S phase cells following thymidine synchronisation. At the indicated times 4×10^7 cells were suspended in 4.0 ml of complete medium at 37° C containing 200 μ Ci of 3H -uridine (specific activity 720 Ci mmol⁻¹, New England Nuclear, Boston, Massachusetts). After incubation for 1 h, cells were washed, resuspended in STE (0.05 M Tris-HCl, pH 7.4; 0.001 M EDTA; 0.1 M NaCl) containing 1% sodium dodecyl sulphate (SDS) and 1% mercaptoethanol, and extracted three times at room temperature with phenol saturated with 20% STE. Nucleic acid was precipitated for 16 h at -20° C with 0.15 M NaCl and 2.5 volumes ethanol. The precipitate was suspended in 1.0 ml HSB (0.01 M Tris-HCl pH 7.4, 0.5 M NaCl and 0.05 M MgCl₂, digested with 100 μ g DNase I at room temperature for 30 min, and the RNA reprecipitated. RNA was dissolved in $2 \times$ SSC and the Cl_2CCOOH insoluble radioactivity and virus-specific radioactivity determined. DNA-RNA hybridisation was carried out in a solution of $2 \times$ SSC containing 7.5 M urea, 10^{-2} M Tes (N-tris (hydroxymethyl) methyl-2-aminoethane sulphonic acid) buffer, pH 7.0, and 0.05% SDS. Equal aliquots of individual samples were incubated with nitrocellulose filters containing 8 μ g of alkali denatured adenovirus 2 DNA and blank filters at 37° C for 4 d. Pancreatic RNase resistant radioactivity was determined. Virus-specific RNA was corrected for recovery from phenol extraction and for nonspecific binding using the amount of radioactivity bound to filters not containing adenovirus DNA. This represented 20-25% of the specific binding. *a*, Colcemid (0.025 μ g ml⁻¹) was added at the beginning of S phase; *b*, colcemid was not added allowing the cells to pass through mitosis into G_1 . ●, Virus-specific radioactivity; ○, total radioactivity; Δ, % metaphase cells.

Table 1 Extent of viral RNA synthesis in G_2

Interval before metaphase (h)	Cell cycle stage	Total c.p.m. $\times 10^7$	Hybridisable c.p.m.
6	S + G_2	3.87	545
4	late S + G_2	1.62	228
2	G_2	0.77	178

The diagram below the table outlines the experiment as described in the text. RNA was extracted and assayed as described in Fig. 2 from metaphase arrested cells. At the end of each incubation period 4×10^7 cells with approximately 60-70% in metaphase arrest were mixed with bovine albumin resulting in a final concentration of 30%. Gradients were formed by successive addition of 1 ml each of the cell mixture, 23%, 20%, and 17% albumin and 0.5 ml of 10% albumin at the top and were centrifuged in a Spinco SW65 rotor at 17,500 r.p.m. for 45 min at 5° C. $2 \times 10^7 - 3 \times 10^7$ cells with a metaphase index of 95-97% were recovered from the 17-10% interphase of two gradients.

During mitosis, the synthesis of viral RNA seemed to be restricted to the same extent as cellular RNA. These data permit the generalisation that the transformed state can be correlated with continuous functioning throughout interphase of at least some portions of the integrated genome. This result is in sharp contrast to that observed with H and L chain biosynthesis¹⁴, induction of tyrosine amino transferase¹⁵, and synthesis of histone mRNA¹⁶, in cultured mammalian cells, none of which is continuous throughout interphase. The relative composition of the RNA transcripts synthesised in each phase must be explored. This analysis seems particularly important, since individual clones of Ad2-T have incorporated not only different portions of the adenovirus genome but also different proportional amounts of the same fragment (J. Sambrook, personal communication). Comparison of the RNA synthesised during the same phase of the cell cycle in different clones may provide information about the site of integration of the viral genome, especially if sufficient quantities of virus-specific RNA can be obtained for limited structural analysis. Of equal importance is the post-transcriptional processing in each phase. We are at present examining whether there is continuous export or selective exit of particular viral transcripts at unique times in the cell cycle. Further investigation with clones containing defined adenovirus segments, when synchronised, should provide useful information concerning both the maintenance of the transformed state and the expression of the host cell genome.

This investigation was supported by a research grant from the United States Public Health Service. S. E. T. and P. M. M. were Postdoctoral trainees and L. D. H. is a recipient of United States Public Health Service Research Career Development Award from the National Institutes of General Medical Sciences.

Fig. 1 Analysis by polyacrylamide gel electrophoresis in SDS-containing buffer of reduced ^{125}I -labelled surface immunoglobulins of chicken bursa lymphocytes. Sample is adult bursa, experiment I, Table 1. ●, Specifically precipitated immunoglobulin (RAFγG + GARG); ○, control precipitate (NRS + GARG). μ, γ and L indicate the positions at which human μ chain, γ chain and light chains migrated in this 9% gel.

Isolation of surface immunoglobulins from lymphocytes from chicken thymus and bursa

ALTHOUGH the chicken is more closely related to dinosaurs and crocodiles than to the mouse¹, the clear-cut demarcation between thymus-derived (T) and bursa-derived (B) lymphocytes in this bird^{2,3} offers an excellent system for study of the two lymphocyte types. B cells have been demonstrated to possess surface immunoglobulin³⁻⁵, while T cells have not, although it has been established that light chains at least are expressed on specifically activated chicken T cells⁶. So far, however, intact polypeptide chains have not been demonstrated on T and B cells. We now describe the isolation and partial characterisation of surface immunoglobulins of chicken B and T lymphocytes. We have evidence that both lymphocyte types have surface immunoglobulins consisting of light chains, μ chains and a heavy chain of molecular weight 40,000.

Lymphocyte suspensions were prepared from thymuses, bursas and spleens of normal chickens (outbred white leghorn-australorp hybrids; newly hatched or 3-4 months old) and thymuses and spleens of hormonally bursectomised⁷ chickens (Table 1). The cell populations were greater than 95% viable and consisted predominantly of lymphocytes (bursa and thymus, approximately 95%; spleen approximately 80%). These suspensions were surface-radioiodinated as previously described (refs 8 and 9 and Table 1 and Figure legends); ^{125}I -labelled surface proteins were extracted by various methods as described in the legend to Table 1, and immunoglobulin was isolated by specific immunological precipitation using antiserum to chicken 7S immunoglobulin (IgY) which possessed activity directed against light chains and the γ (Y) heavy chain.

As Table 1 shows, ^{125}I counts were specifically precipitated from labelled surface protein preparations obtained from thymic, bursa and splenic lymphocytes. In one case where thymus cells of neonatal chickens (day 1) were extracted with 1% Nonidet P-40, 6 M urea (apparent pH 7.2) no significant ^{125}I counts were precipitated by antiserum to chicken immunoglobulin. Because the other thymus lymphocyte preparations contained specifically precipitable immunoglobulin, we believe that the negative result represents a technical problem which arises from the release of proteolytic enzymes during the lysis of whole cells with the detergent urea mixture (D. Hausteine and J. J. M., unpublished observations). Between 1.5 and 3.5% of ^{125}I -iodide counts in high molecular weight cell surface protein

of bursal lymphocytes were precipitated as immunoglobulin. Corresponding results for thymus lymphocyte populations varied from 1.0 to 2.4% under these conditions.

Although these results show that surface immunoglobulin can be isolated from chicken lymphocytes, they tell nothing about the class of such immunoglobulins because the antiserum used possessed activity for light chains. To investigate this problem we dissolved the precipitates in 3% sodium dodecyl sulphate (pH 6.8) containing 10% glycerol, 6M urea and 2% mercaptoethanol to cleave interchain disulphide bonds, and resolved heavy and light polypeptide chains by electrophoresis in 9% (w/v) polyacrylamide gels under conditions described by Laemmli¹⁰. Figures 1 and 2 illustrate the polypeptide chain distribution patterns for adult (3 months) bursal lymphocytes (Fig. 1) and neonatal thymus lymphocytes (Fig. 2). These patterns are representative of all experiments. In both cases illustrated, components with mobilities characteristic of μ chains and light chains were resolved. Each pattern also contained a component with a relative mobility of approximately 0.5 which corresponded to a molecular weight of about 40,000 in terms of the standard proteins used. High molecular weight aggregate which did not enter the gel was also present in all chicken samples analysed. No definite components resembling the chicken γ (Y) chain (molecular weight 65,000; ref. 11) were found in any preparations.

Fig. 2 Analysis by polyacrylamide gel electrophoresis in SDS-containing buffer of reduced ^{125}I -labelled surface immunoglobulins on neonatal thymus lymphocytes (experiment IV, Table 1, turnover sample). ●, Specifically precipitated sample (FγG + RAFγG); ○, control, precipitate (MγG + RAMγG). μ, μ chain (chicken); γ (Y) chicken γ (Y) heavy chain; γ, human γ chain; ALD, aldolase; L, light chain (chicken). 9% polyacrylamide.

Table 1 Isolation of ^{125}I -labelled surface immunoglobulin from chicken lymphocytes

Experiment	Cell source	Extraction procedure	Specific system	(¹²⁵ I-iodide in precipitate)	Control system	Difference	% Initial counts (high mol. wt protein in sample) precipitated as Ig
I	Bursa (adult)	Turnover	12,600 ± 700 (a)	3,600 ± 100 (b)	9,600	1.5	
II	Bursa (neonatal)	Turnover	15,000 ± 940 (c)	2,400 ± 90 (d)	12,600	3.5	
III	Bursa (neonatal)	Turnover	9,600 ± 600 (c)	1,200 ± 50 (d)	8,400	3.5	
		Acid-urea	4,800 ± 350 (c)	1,200 ± 80 (d)	3,600	3.2	
IV	Thymus (neonatal)	Turnover	8,300 ± 700 (c)	2,800 ± 30 (d)	5,500	2.4	
		Nonidet P-40 extract of pellet	11,700 ± 1,300 (c)	4,100 ± 300 (d)	7,600	0.6	
V	Thymus (bursectomised)	Nonidet P-40 urea	1,800 ± 200 (c)	1,500 ± 80 (d)	N.S.	—	
VI	Thymus (bursectomised)	Acid-urea	3,900 ± 300 (c)	900 ± 70 (d)	3,000	1.0	
	Spleen (bursectomised)	Acid-urea	2,500 ± 130 (c)	300 ± 20 (d)	2,200	0.7	
	Thymus (normal)	Acid-urea	5,900 ± 120 (c)	2,000 ± 40 (d)	3,900	1.3	
	Spleen (normal)	Acid-urea	1,100 ± 40 (c)	400 ± 30 (d)	700	0.5	
	Bursa (normal)	Acid-urea	12,600 ± 400 (c)	4,900 ± 130 (d)	7,700	2.5	

Chicken lymphocytes were radioiodinated as follows. To 10^7 lymphocytes in 50 μl phosphate buffered saline (0.02 M phosphate; 0.15 M NaCl, pH 7.2) containing 20 μg lactoperoxidase (either prepared by the method of Morrison and Hultquist²³ or purchased from J. L. B. Laboratories, Granada Hills, California) were added 4 μl (approximately 300 μCi) carrier-free ^{125}I -iodide (Radiochemical Centre, Amersham). The reaction was initiated by addition of 10 μl of 0.03% H_2O_2 followed by mixing. The cells were incubated at 30°C for 5 min, after which the reaction was stopped by addition of large volumes of chilled phosphate buffered saline (PBS). Cells were washed twice at 4°C by centrifugation before lysis or metabolic release. Uptake of ^{125}I -iodide ranged from 10–20% of the initial amount. Between 5 and 10% of this cell-associated value was high molecular weight as judged by dialysis or trichloroacetic acid precipitation. Metabolic release (turnover) of surface immunoglobulins of labelled cells was achieved as before²⁴. For extraction with Nonidet P-40 cells were incubated in 0.5% Nonidet P-40 in PBS at a concentration of 10^7 cells ml for 15 min at room temperature. Nuclei and insoluble particulate matter were removed by centrifugation. Acid-urea extraction was performed as described elsewhere⁹. In extraction with Nonidet P-40 urea, the cells were dissolved in 1% Nonidet P-40–6M urea; otherwise the conditions were as described above. All samples were dialysed against 0.15 M NaCl buffered to pH 8.0 with Tris-HCl before immunological analysis. Coprecipitated samples were washed three or four times. Data given here refer to ^{125}I counts (means \pm s.e. of at least four replicates) associated with specific or control precipitates. Precipitation systems were (a) rabbit antiserum to chicken IgG (Y) immunoglobulin (contains specificity for light chains and γ (Y) chains) plus goat antiserum to rabbit IgG (Commonwealth Serum Laboratories, Melbourne); (b) normal rabbit serum plus goat antiserum to rabbit IgG; (c) carrier chicken IgG (Y) plus rabbit antiserum to chicken IgG (Y), and (d) mouse IgG plus rabbit antiserum to mouse IgG. All systems were calibrated to precipitate more than 90% of their homologous antigen. Data given represent counts from $2\text{--}5 \times 10^6$ lymphocytes.

A significant finding was the release of IgM by turnover from thymuses of newly hatched chickens. In these chickens the only existing immunoglobulin is maternal IgG (Y) released from the yolk, and there is no detectable IgM in the serum¹². A second significant finding was that chicken bursa lymphocytes express surface immunoglobulin polypeptide light chains, μ chains and a component of molecular weight 40,000. It is not surprising to find light chains and μ chains because several workers using methods similar to ours isolated IgM immunoglobulin from human¹³ and murine^{14,15} B lymphocytes. The 40,000 molecular weight component was unexpected, but is consistent with the report that chicken B lymphocytes synthesise and apparently express on their surfaces a component of similar size which is antigenically related to μ chain¹⁶ and termed H_μ chain. A heavy chain of this size is interesting from an evolutionary viewpoint because the major immunoglobulin class in certain reptiles¹⁷ and birds¹⁸ contains a heavy chain of mass approximately 40,000 daltons. This heavy chain has been termed the nu chain¹⁹. Although such a component is not readily detectable in chicken serum, it might constitute an important surface-associated receptor molecule in this species. We do not believe that this surface-associated heavy chain is a degradation product of μ chain because of the biosynthetic results of Choi and Good¹⁶ and because the molecule has been obtained under conditions where we have not observed proteolysis in studies of mammalian

lymphocyte surface immunoglobulin²⁰. Ladoulis *et al.*²⁵ reported immunoglobulins of molecular weight 200,000 and 130,000 on the plasma membranes of rat thymus and spleen lymphocytes. The chicken surface immunoglobulins tended to aggregate and we could not estimate intact molecular weights. If they consist of L_2H_2 units analogous to surface immunoglobulins of man^{13,15,20} and mouse^{14,15,20}, they should have molecular weights of about 185,000 and 125,000.

Our finding of immunoglobulins consisting of μ and light chains on chicken T cells is consistent with similar studies of mammalian T cells^{15,20,21}. Biosynthesis has demonstrated immunoglobulin in thymocyte populations of normal chickens²² and Theis and Thorbecke⁶ inhibited specific delayed type hypersensitivity reactions in bursectomised chickens by antisera to immunoglobulin, concluding that chicken T lymphocytes have at least light chain antigenic determinants on their surfaces. We have now established that such cells also express μ chains and a chain similar to the H_μ heavy chain described by Choi and Good¹⁶. Because our method gives a bulk average, it is not possible to decide whether μ chain and H_μ chain occur on the same T or B lymphocytes.

The existence of IgM on the surface of mammalian T cells has been confirmed independently in several laboratories^{21,25,26}. The presence of IgM on the thymocytes from newly hatched chickens which lack detectable circulating IgM, makes it improbable that

this immunoglobulin has been adsorbed from the serum.

Effect of T cell depletion on the potentiated reagin response

In the rat, infection with helminth parasites can have the remarkable effect of causing nonspecific potentiation of IgE (reaginic) antibody responses against antigens unrelated to those of the parasite. This phenomenon, which has been called the potentiated reagin response¹, has been found to encompass IgE responses to antigens as diverse as egg albumin, keyhole limpet haemocyanin and house dust² and has been produced with representatives of both nematode and trematode parasites³.

The potentiated reagin response is but one manifestation of the potent IgE stimulating effect⁴ of helminths. Infections with these parasites also induce high levels of reaginic antibody specific for parasite derived antigens, and at least in man, cause greatly elevated levels of total serum IgE. Parasite-specific reagins which were first described in in-

fections of the rat with *Nippostrongylus brasiliensis* and the rat and monkey with *Schistosoma mansoni*⁵ have been demonstrated in various host-parasite systems in many species including man^{5,6}.

The potentiated reagin response provided a basis for experimental investigation of the mechanism of IgE stimulation in helminth infections. It is known that parasitic infection can only amplify an already existing IgE response: in the rat this must be induced before infection by inoculation of the antigen together with a conventional adjuvant^{1,7}. IgE responses against different antigens may be simultaneously potentiated² while IgG responses remain largely unaffected^{7,8}. The indications from these results are that live worms produce a factor which has the capacity to stimulate those immunocytes previously programmed for IgE production.

To find out whether this factor acts directly on IgE-producing B cells or whether its effect is produced through T cells, we examined the effect of T cell depletion and show here that this prevents potentiation of reagin responses in rats infected with the nematode *N. brasiliensis*.

Outbred female Hooded Lister rats (Animal Suppliers (London) Ltd), were used. Thymus deprived (B) rats were prepared by thymectomy at 4 weeks of age, followed by 850 rad whole body irradiation 2-4 weeks later. During

Fig. 1 Mean EA reaginic antibody levels 4 d before (□) and 14 d after (▨) *N. brasiliensis* infection. Eighteen B rats, 10 normal control rats and 8 irradiated control rats were immunised with 1 mg EA (58 d after thymectomy; 38 d after irradiation). Of these 9 B rats, 10 normal rats and 6 irradiated rats produced an EA IgE response and were infected with *N. brasiliensis* 28 d after immunisation. The means and standard errors shown above were calculated using logarithmically transformed antibody titres.

Fig. 2 Prolonged egg output in B rats (○) infected with *N. brasiliensis* compare with infected normal rats (●). Groups of 10 B rats and 5 normal rats were killed 19 d after infection when mean worm burdens in the small intestine were found to be 618 ± 255 (s.e.) for the B rats and 3 ± 2 (s.e.) for the normal controls. Of these animals 5 B rats and 5 normal rats had detectable circulating *N. brasiliensis* reagins and the mean levels (\pm s.e.) are shown above.

irradiation the distal parts of both hind limbs were shielded to allow auto-repopulation by bone marrow cells. This technique⁹ has been shown to produce animals whose T deficiency resembles that of thymectomised animals prepared by irradiation and reconstitution with bone marrow cells. The animals were immunised 1–2 months later by intraperitoneal inoculation of 1 mg of either egg albumin (EA) (Sigma grade 5) or keyhole limpet haemocyanin (KLH) (Cal Biochem A grade) together with 10^{10} *Bordetella pertussis* organisms (Wellcome Biological Reagents). At appropriate times after immunisation, the animals were bled from the tail vein and IgE antibody levels were determined by titration of individual sera by the passive cutaneous anaphylaxis (PCA) technique¹⁰. The IgE-producing B rats together with IgE-producing normal rats were then infected by subcutaneous inoculation of 4,000 *N. brasiliensis* larvae and were bled for antibody estimations 12–14 d later when the potentiated reagin response normally reaches its peak.

Table 1 shows the results of one such experiment involving groups of B and normal rats immunised with either EA or KLH. It can be seen from the individual titres that whereas reagin responses were markedly potentiated in eight out of ten normal animals a significantly raised response occurred in only one of ten B rats. This latter animal is in fact the only B rat in which potentiation has occurred in four experiments.

Figure 1 shows the results of another similar experiment which included an additional control group of rats which had been irradiated without previous thymectomy. Again it is clear that the parasitic infection did not have any significant effect on the levels of EA reagin antibody in B rats whereas the response of the normal animals was substantially raised. The results also show that the process of irradiation does not in itself interfere with the ability to form potentiated reagin responses. Two other experiments were performed which gave consistent results.

In these experiments we also studied some parameters of the immune response to the parasite itself since T-cell deficiency has been described as depressing immune responses in parasitic infections^{11,12}. In normal adult rats,

Table 1 Effect of *N. brasiliensis** infection on egg albumin (EA) and keyhole limpet haemocyanin (KLH) IgE responses in normal and thymus deprived (B) rats.

The Hooded Lister strain of rats which we use normally produce a good IgE response on immunisation with doses of EA as low as 1 μ g (ref. 18). Preliminary experiments with B rats showed that these did not have an IgE response following doses of 10 μ g EA but that 33–50% did so following doses of 1 mg EA. The ability to overcome effects of T cell deficiency by increasing the antigen dose has been reported in other systems^{19,20}. In this experiment, 27 B rats were divided into groups of 15 and 13 and the animals of each group were immunised with 1 mg EA or KLH respectively (44 d after thymectomy, 30 d after irradiation). Groups of normal rats were similarly immunised. Five animals in each of the B groups developed a reagin antibody response and they, together with a similar number of normal control animals, were infected with *N. brasiliensis* 26 d after immunisation.

* The method of culture of *N. brasiliensis* and preparation of the infective larval dose have been previously described^{21,22}.

† To estimate reagin antibodies by the PCA technique 0.1 ml quantities of saline dilutions of the test sera were injected intradermally in Hooded Lister recipient rats, each injection being duplicated on a different animal. 48–72 h later the animals were injected intravenously with 2.5 mg of either EA or KLH together with 0.5 ml of 1% Evans blue which acts as an indicator of vasodilation. The skin reactions were examined after 20 min and the titres recorded above are the greatest dilutions of serum which gave reactions larger than 5 mm in diameter.

primary infection with *N. brasiliensis* is followed 10–12 d later by an immunological expulsion of worms from the small intestine. This so called 'self-cure' reaction proceeds exponentially over several days and is preceded by a fall in egg production by the parasite. Reagin antibodies specific for *N. brasiliensis* appear during or shortly after worm expulsion and rise to reach high circulating levels. These manifestations of parasitic immunity were found to be markedly depressed in the B rats in our experiments. Egg production continued for a longer period than in the control animals, the expulsion rate of worms was decreased and the parasite specific IgE response was depressed or undetectable (Fig. 2).

Although it seems clear that T cells are involved in the potentiation of existing IgE responses by *N. brasiliensis* infection, their mode of action is still conjectural. Other workers using hapten-carrier immunisations have shown that carrier-specific T cells are heavily involved both as helpers^{13–15} and suppressors^{16,17} of B cells in anti-hapten IgE responses of rats and mice. In these situations, the T cell effect is antigen specific. The potentiated reagin response on the other hand is a nonspecific event and any theories about its mechanism must accommodate this element of nonspecificity as well as the requirement for T cells and the fact that it is only, or largely, IgE responses which are affected. T cells are known to produce a variety of soluble factors which can affect both cell-mediated and humoral immunity and it would seem most likely that it is through such factors that they exert their role in the potentiated reagin response.

Assuming that T cells exert a helper effect, potentiation could be brought about in one of two ways. In the first,

the parasite-derived potentiating factor activates a population of T cells to produce a substance which is capable of selectively stimulating IgE B cells regardless of their antigenic specificity. In the second, the parasitic factor activates T cells so that those which have preordained IgE helper functions (induced by previous immunisation) are driven to perform them. In the latter mechanism, the T cell effects on the B cell is antigen specific. It is equally possible that the potentiation of reagins is the result of release of B cells from the inhibiting effect of suppressor T cells but, in essence, the mechanisms outlined above would remain the same.

This work was supported by grants from the Medical Research Council, the Asthma Research Council and Fisons Ltd, Pharmaceuticals Division. E. J. was in receipt of a fellowship from the Scottish Home and Health Department. We thank Diana Stewart and David Haig for their assistance and Jean Laurie for irradiating the rats.

homogeneous populations of glucocorticoid target cells has advanced our understanding of the molecular mechanisms involved^{2,3}. Using a specific antiserum we have now shown that cortisol induces glycerol phosphate dehydrogenase (GPDH, EC 1118) in a rat brain tumour cell line by increasing the number of GPDH molecules rather than by increasing the activity of each molecule. Also, the induction does not involve isozymes since GPDH from induced and uninduced cells is identical with respect to immunological titration, electrophoretic mobility and thermal sensitivity.

Fig. 1 Immunological titration of GPDH from control and cortisol-induced cells. Cells were grown in Ham's F-10 medium supplemented with 10% foetal calf serum, in Falcon T-250 plastic flasks as described previously^{6,8}. Cortisol (when present) was added to a final concentration of $0.5 \mu\text{g ml}^{-1}$ for 3 d before collection. The cells were first washed twice with 3 ml volumes of 10 mM Na phosphate buffer, pH 7.5, containing 5 mM mercaptoethanol and 1 mM EDTA and then were collected in 1 ml of the same buffer using a rubber policeman to scrape the cells from the flask. After disruption by sonication cellular debris was removed by centrifugation for 1 h at 30,000 r.p.m. in a 30 rotor using a Beckman L2-65-B ultracentrifuge. The supernatants from induced and uninduced cells were assayed for GPDH activity as described previously¹⁵ and the concentration of enzyme was equalised by concentrating the supernatant from uninduced cells using an Amicon ultrafiltration apparatus (PM30 membrane). Rabbit antiserum against purified rat brain GPDH was obtained as described previously¹⁵. The serum was initially diluted in 0.01 M phosphate buffer, pH 7.5 containing 1 mg of bovine serum albumin ml^{-1} , 1 mM EDTA and 5 mM mercaptoethanol and from this stock solution a series of dilutions of antiserum was made. A sample of 0.2 ml of each of the dilutions was added to tubes in triplicate. The high speed supernatant from induced and uninduced cells was used as the source of GPDH and a constant amount (0.1 ml, 200 U ml^{-1}) was added to each tube. After incubation at 37°C for 30 min an aliquot was removed and remaining GPDH activity was determined. Incubation overnight at 4°C did not result in further inactivation of GPDH and since the antibody-GPDH complex was enzymatically inactive it was not necessary to centrifuge the samples. The amount of enzyme remaining after incubation with antiserum was subtracted from that present in the absence of antiserum and the results were plotted as the number of units of enzyme removed against the microlitres of antiserum present. O, GPDH from uninduced cells; ●, GPDH from cortisol induced cells.

Cortisol induction of glycerol phosphate dehydrogenase in a rat brain tumour cell line

HORMONAL regulation of enzyme levels in mammalian cells has been known for more than a decade¹ and the use of

The increase in the level of brain GPDH during the development of the rat is regulated specifically by cortisol¹. This hormonal dependence has also been demonstrated in primary cultures of brain cells⁵ and in RGC6 (C6) cells⁶, a line of rat glial tumour cells⁷. The addition of cortisol or other glucocorticoids^{8,9} to confluent C6 cells increases GPDH activity three-fold within 24 h and up to ten-fold over 5 d. This induction requires RNA synthesis, protein synthesis and the continual presence of cortisol^{6,9}.

Simple explanations for this increased activity—a direct effect of cortisol in the assay, increased overall protein synthesis and the presence of diffusible inhibitors or activators—have been ruled out⁶. We have investigated which of the alternative mechanisms is responsible for cortisol-dependent increase in GPDH in C6 cells. An increase in enzyme specific activity can occur if the catalytic activity of each molecule increases^{10,11} or if the number of molecules increases^{2,3,12,13}. These mechanisms are not mutually exclusive nor are they comprehensively explanatory since each could be achieved by various changes in the regulatory machinery of the cell.

Using rabbit antiserum directed against rat brain GPDH,

Fig. 2 Electrophoresis of GPDH from C6 cells (clone 2B-13). The cells were grown and collected as described in Fig. 1. Electrophoresis was by the method of Davis¹⁸ and the gels were stained for GPDH activity as described previously¹⁵. Each gel contained a total of 20 U of GPDH, where 1 U of activity is equal to the amount of enzyme which oxidises 1 nmol of NADH min⁻¹ under the conditions of the assay. Supernatants were from induced cells (a), uninduced and induced cells (b) and uninduced cells (c).

Fig. 3 Heat inactivation of GPDH from induced and uninduced cells. Cells were grown and collected as described in Fig. 1. Before concentration by ultrafiltration, the specific activities of GPDH in the high speed supernatants were 45 U mg⁻¹ of protein and 188 U mg⁻¹ of protein, for uninduced and induced cells respectively. The concentrations of GPDH at the zero time points (100% activity) were 207 U mg⁻¹ for the induced (O), 206 U mg⁻¹ for the uninduced (Δ) and 214 U ml⁻¹ for the mixture (□) containing equal amounts of induced and uninduced enzyme activity. For clarity the data from the mixture are plotted using the ordinate on the right. Three sets of tubes (in duplicate) containing 200 μl of each of the enzyme solutions were incubated in a circulating water bath at 50.0 ± 0.05° C for the indicated times. The tubes were sealed with parafilm to prevent evaporation. Immediately after removal from the bath, the samples were quickly cooled by swirling in an ice-salt slurry (-15° C) for 5 s and were then maintained at 0° C until completion of the experiment. Aliquots from each tube were assayed as described¹⁵.

we have distinguished between the above mechanisms (Fig. 1). If the induction represents an increased number of molecules then equal amounts of antiserum will be needed to inactivate the same number of GPDH units from either induced or uninduced cells. If the induction is due to an increased activity per molecule then the amount of antiserum required to inactivate the same number of enzyme units from each source will be different. Figure 1 shows that equal amounts of enzyme are inactivated by equal amounts of antiserum. Therefore, the cortisol-dependent increase in GPDH activity in C6 cells represents an increase in the number of enzyme molecules.

The existence of more than one enzyme able to catalyse the same reaction has been known for some time. GPDH isozymes have been isolated from tissues of various species and at least two forms of GPDH have been demonstrated in mouse brain¹⁴, while two distinct GPDH have been purified from rat brain¹⁵. In addition, the basal level of

GPDH in C6 clones¹⁶ and in hybrids¹⁷ is apparently regulated independently of the induced level of GPDH. Such data are consistent with the possibility that there is more than one structural gene for GPDH.

Since two electrophoretically distinct forms of GPDH have been purified from rat brain¹⁵, we examined the mobility of GPDH by polyacrylamide gel electrophoresis as a test of the identity of GPDH in hormone-treated and untreated cells. Only one form of GPDH was found in induced (Fig. 2a) and uninduced (Fig. 2c) C6 cells. In addition, since only one band of enzyme activity was found when a mixture was run (Fig. 2b), we conclude that the GPDH in induced cells is electrophoretically identical to that in uninduced cells. Identity by polyacrylamide gel electrophoresis is not definitive proof that the basal enzyme is identical to the induced form, but shows that one of them does not represent an oligomeric form of the other and that there is no net charge difference between them.

Further confirmation of the identity of the induced and basal forms of GPDH was obtained from heat denaturation experiments. The ability of GPDH from control and treated cells to survive heating at 50° C (Fig. 3) showed that there was only one heat labile component in induced and uninduced cells. The single straight line obtained when supernatants from induced and uninduced cells are mixed and heated indicates that the GPDH from both sources is identical. These results, together with the electrophoretic and immunological data, argue against the possibility that the induction of GPDH activity in C6 cells involves the formation of an isozyme. The sensitivity of these procedures in detecting isozymes has been discussed¹⁸ and more recently similar techniques were used to demonstrate the absence of isozymes in tyrosine aminotransferase induction in hepatoma cells²⁰.

We are now investigating the mechanism(s) by which the number of GPDH molecules increases. Obviously an increase in the rate of synthesis^{12,13} of the enzyme or a decrease in its rate of degradation²¹ or a combination of these could lead to an accumulation of GPDH molecules. The determination of the specific rates of synthesis and degradation will allow us to distinguish between these possibilities.

***In vitro* restoration of deficient β -galactosidase activity in liver of patients with Hurler and Hunter disease**

HUNTER'S and Hurler's syndromes are recessively inherited errors of metabolism, in which accumulation of mucopolysaccharides in tissues is accompanied by skeletal abnormalities and mental retardation. Patients suffering from these diseases show a strikingly reduced activity of β -galactosidase in the liver although this enzyme is not directly involved in the degradation of the glycosaminoglycans that accumulate in the tissues¹⁻³. This enzyme reduction which is accompanied by an abnormal isoenzyme pattern⁴ can be understood as the result of complex formation between stored mucopolysaccharides and the β -galactosidase enzyme. Indeed artificial mixtures of chondroitin sulphate and liver β -galactosidase show an isoenzyme profile quite analogous to that seen in Hurler's and Hunter's diseases⁵. The isoenzyme abnormality and the reduction in enzyme activity of such an artificial mixture can be neutralised by cetylpyridinium chloride (CPC), a quaternary base which is known to form complexes with mucopolysaccharides⁶. Therefore it seemed possible to restore the β -galactosidase activity of the Hurler and Hunter patients.

When increasing amounts of CPC were added to a liver homogenate from four patients with Hunter's or Hurler's syndromes a striking increase in β -galactosidase was seen, up to a CPC concentration of about 25 μ g per mg liver (Fig. 1). But with still higher concentrations of CPC, enzyme activity was strongly reduced almost to nothing. The maximum activation corresponded only to a partial restoration of the β -galactosidase activity. This can be explained on the assumptions⁷: (1) that CPC dissociates the complex of mucopolysaccharides and β -galactosidase with restoration of enzyme activity; and (2) that CPC itself is a strong inhibitor of free β -galactosidase (that is, without bound chondroitin sulphate). The latter statement is supported by the fact that in the homogenate of a normal liver, strong inhibition of the enzyme activity is seen (Fig. 1).

In order to obviate the CPC drawback, I tried to dissociate the complex using other methods. Addition of albumin in acid medium seemed appropriate because of the possible precipitation of mucopolysaccharides with acidified solutions of albumin⁷. When increasing amounts of albumin were added to the homogenates of the patients' liver, β -galactosidase rose about five- to ten-fold, whereas in a normal liver an activation of only 10% was found. The restoration resulted in an essentially normal activity in the livers from two patients, while for the two other patients a final activity of about 40% of the mean normal value was achieved (Fig. 2). The highest restoration was found in the liver which had been stored for the shortest time.

It seems unlikely that therapeutic applications can result from the data presented here. If the albumin concentration

Fig. 1 Influence of increasing amounts of cetylpyridinium chloride on β -galactosidase activity in human liver homogenates of *a*, normal; *b*, Hunter; *c-e*, Hurler individuals. Autopsy material from patient *c* had been stored at -20°C for 4 yr while the three other liver pieces were stored for 7 yr. Liver homogenates (4% v/v) in distilled water were centrifuged after sonicating for 60 s and five cycles of freezing and thawing. Increasing amounts of CPC in distilled water were added to the supernatant of each individual and β -galactosidase activity was then measured as described⁶.

of the *in vitro* experiments reflect the conditions for *in vivo* restoration, high intracellular concentrations of albumin are necessary. Moreover, the restoration of β -galactosidase activity will result in only a minor attack on the stored material. Only the accumulated galactose-containing glycolipids and gangliosides will be broken down, while the fundamental absence of α -iduronidase⁸, sulpho-iduronosulphatase⁹, and N-acetyl- α -glucosaminidase^{10,11} will not be corrected by the albumin treatment.

But, if the mental deficiency of patients with mucopolysaccharidosis is due to the neuronal accumulation of the glycolipids, *in vivo* restoration of β -galactosidase by infusion of large amounts of albumin early in life, might nevertheless be beneficial.

Fig. 2 Influence of increasing amounts of albumin on β -galactosidase activity in liver homogenates from *a*, control; *b*, Hunter; *c-e*, Hurler individuals. Legend and methods as in Fig. 1, but albumin in acetate buffer (0.2 M, pH=4.5) was added to the liver homogenate instead of CPC. The range of normal values is shown at the upper right. The arrow indicates the mean value of the enzyme activity in eight control autopsy livers.

I thank Dr J. O'Brien of the University of California at La Jolla for providing liver autopsy material.

Aspirin, indomethacin, catecholamine and prostaglandin interactions on rat arterioles and rabbit hearts

VANE *et al.* have demonstrated that antipyretic, anti-inflammatory drugs can inhibit prostaglandin synthesis and release¹⁻³. We have investigated the effects of aspirin on the responses of rat arterioles to noradrenaline.

Using male, 150 g, Sprague-Dawley rats anaesthetised with ether we cannulated the superior mesenteric artery, dissected out the mesenteric part of its vascular bed and mounted the preparation in an organ bath⁴. We perfused the artery with Krebs bicarbonate buffer at 37°C , bubbled with 5% carbon dioxide in oxygen. After an equilibration period of 30 min we adjusted the flow rate so that the pressure in the arterial cannula had a mean value of about 80 mm Hg. The flow rate was then left constant for the remainder of the experiment. The baseline pressure remained steady (variation less than 10%) for periods as long as 3 h (Fig. 2). The preparation responds to injection of vasoconstrictor drugs by a rise in arterial pressure. The maximal pressor response to constrictor drugs is usually in the region of 80-120 mm Hg above baseline. Noradrenaline solution (0.1 ml) in 0.9% saline was injected into the arterial cannula at regular intervals. Each preparation was tested with a range of noradrenaline concentrations to find one which gave a pressure rise of about 70 mm Hg. This was usually about 1 ng ml^{-1} solution. This concentration was then used for the rest of the experiment. Each injection produced a transient rise in pressure which returned to baseline within about 1 min. Once three pressor responses of constant amplitude ($\pm 10\%$) had been obtained, the formal experiment was started, results being expressed as percentages of the mean initial response.

Aspirin was added to the perfusate in three concentrations 5, 10 and $20\text{ }\mu\text{g ml}^{-1}$ (Fig. 1). The results demonstrate a reversible depression of responsiveness to noradrenaline, the constrictor effect being eliminated by an aspirin concentration of $20\text{ }\mu\text{g ml}^{-1}$. Baseline perfusion pressure was not altered.

The abolition of responsiveness might be explained by pH changes, a direct action of aspirin itself on the interaction between noradrenaline and muscle receptors, on excitation-contraction coupling or on the contractile process,

or an indirect action of aspirin depending on its suppression of prostaglandin synthesis. The $20 \mu\text{g ml}^{-1}$ aspirin concentration produced a pH change of less than 0.1 unit and changes of 0.3 unit produced by adding acetic acid to the buffer caused no significant changes in responsiveness. In five experiments indomethacin, another suppressor of prostaglandin synthesis, in a concentration of $5 \mu\text{g ml}^{-1}$ also produced a complete abolition of responsiveness. We therefore attempted to reverse the effect of aspirin by adding prostaglandin E_2 to aspirin-blocked preparations (Fig. 2).

A prostaglandin E_2 concentration of 1 pg ml^{-1} produced partial restoration of responsiveness. Above 10^3 pg ml^{-1} the relationship between E_2 concentration and responsiveness to noradrenaline flattened and no further increase could be demonstrated above 10^4 pg ml^{-1} . Furthermore at an E_2 concentration of 10^4 pg ml^{-1} the two noradrenaline doses used produced essentially the same responses: sample testing with higher noradrenaline concentrations demonstrated that this was a maximal response under these conditions. Restoration of the control perfusion fluid for 30 min showed that the initial control responsiveness could be nearly restored. Addition of prostaglandin $\text{F}_{2\alpha}$ to the perfusion fluid in concentrations up to 100 ng ml^{-1} failed to restore responsiveness. Prostaglandin E_1 had a weak action, being about 100 times less effective than prostaglandin E_2 .

Possible explanations for the results are that endogenous prostaglandin synthesis may be necessary for the combination of noradrenaline with its receptor site or for the chain of events which occur between catecholamine-receptor combination and contraction. The mechanism is not specific to alpha receptors since we have also shown that the vasoconstrictor effects of vasopressin and angiotensin can also be abolished by either aspirin or indomethacin and restored by prostaglandin E_2 . In contrast in five experiments using a rabbit Langendorff perfused heart preparation the chronotropic and inotropic beta actions of adrenaline were not inhibited by concentrations of indomethacin up to $50 \mu\text{g ml}^{-1}$. This raises the interesting possibility that one difference between alpha and beta effects of catecholamines may be that the former require prostaglandins and the latter do not.

Fig. 1 Changes in responsiveness of the rat mesenteric vascular bed to noradrenaline brought about by adding aspirin to the perfusing fluid. Six experiments were performed. Bars indicate 15 min periods during which aspirin was added to the perfusing fluid; concentrations: a, $5 \mu\text{g ml}^{-1}$; b, $10 \mu\text{g ml}^{-1}$; c, $20 \mu\text{g ml}^{-1}$. Before, between and after the bars the preparation was perfused with Krebs-bicarbonate buffer.

Fig. 2 Responses of the aspirin-blocked rat mesenteric preparation to noradrenaline in the presence of various concentrations of PGE_2 . Closed circles indicate responses to 0.1 ml of a noradrenaline concentration sufficient to produce a pressor response in the initial control period of about 70 mm Hg; closed squares indicate responses to 0.1 ml of a noradrenaline solution of half that concentration. During each test the lower concentration was given first and the higher after the first response was completely over. Open circles indicate the baseline pressure. Five experiments were performed and each point represents the mean pressure rise \pm s.e.m. The pairs of noradrenaline injections were given at five minute intervals. After initial control (C) responses aspirin was added to the perfusate in a concentration of $30 \mu\text{g ml}^{-1}$ in order to block responsiveness completely. While maintaining the aspirin perfusion, progressively increasing concentrations of PGE_2 (Upjohn) were added to the perfusate, perfusion of each concentration being maintained for 15 min. At the end of the experiments Krebs-bicarbonate buffer was perfused through the preparation for 30 min. The last two C (control) responses were the pressor effects obtained 20 and 30 min after returning to the Krebs solution.

Syntheses of amino acids from aliphatic carboxylic acid by glow discharge electrolysis

Glow discharge electrolysis (GDE)^{1,2} has been studied mainly on inorganic compounds such as water, ammonia,

and metal ions in aqueous solutions. Little study has been done, however, on the chemistry of GDE using organic compounds³⁻⁷ although experimental results indicate that the application of GDE to organic compounds is a promising area in chemistry and is especially interesting in connection with the concept of chemical evolution.

Here we report representative results of amino acid

formation by contact glow discharge electrolysis (CGDE)^{1,2,8} from several aliphatic carboxylic acids by direct amination using ammonia in aqueous solution.

Two types of electrolysis tubes were used for CGDE; one a U-shaped tube, the other a single tube. In the U tube, the cathode and anode compartments were separated by a fine-porosity glass frit and CGDE was carried out in the

Fig. 1 *a*, A, B, C, D, unknown; E, glycine; F, unknown + buffer change. Reaction conditions: electric current, 65 mA; reaction temperature, 15° C; reaction time, 6 h. The yield of glycine (peak E) was 3.5% from sodium acetate. *b*, A, B, C, unknown; D, glycine; E, alanine; F, unknown; G, β -alanine. Reaction conditions: electric current, 75 mA; reaction temperature, 15° C; reaction time, 3 h. Alanine (peak E, yield 6.9%) was synthesised by amination of the α -carbon of propionic acid. β -Alanine (peak G, yield 5.3%) was formed by amination of the β -carbon. A small amount of glycine (peak D) was formed by the splitting of the α - β carbon linkage. The glycine formation by α - β cleavage of carboxylic acid is a general phenomenon in GDE experiments. *c*, A, B, C, unknown; D, aspartic acid; E, F, unknown; G, glycine; H, alanine; I, unknown; J, β -alanine. Reaction conditions: electric current, 50–70 mA; reaction temperature, 15° C; reaction time, 6 h. The major amino acid product is aspartic acid (peak D, yield 9.1%). Glycine (peak G, yield 0.5%) was formed by α - β bond cleavage. Alanine (peak H, yield 0.3%) was formed by β -decarboxylation, and β -alanine (peak J, yield 1.6%) was formed by α -decarboxylation of aspartic acid. In the several aspartic acid formations, a peak corresponding to β -hydroxy aspartic acid (peak C) was usually found with aspartic acid. The nature of the amino acid at peak C, however, is not yet fully characterised. Similarly, peaks corresponding to threonine and serine (peaks E and F) were commonly found in the reaction products of GDE experiments. These are also not yet characterised. *d*, A, B, C, D, unknown; E, glutamic acid; F, glycine; G, alanine; H, α -aminobutyric acid; I, unknown. Reaction conditions: electric current, 75 mA; reaction temperature, 15° C; reaction time, 3 h. The main

product was glutamic acid (peak E, yield 3.1%). Glycine (peak F, yield 0.8%) and alanine (peak G, yield 0.2%) were also formed. The peak of an expected product, β -aminoglutaric acid, was not identified. *e*, A, B, C, unknown; D, aspartic acid; E, F, unknown; G, glycine; H, alanine; I, J, unknown; K, β -alanine. Reaction conditions: electric current, 75 mA; reaction temperature, 5° C; reaction time, 3 h. After the reaction was over, the ammoniacal solution was evaporated under reduced pressure, and the residue was hydrolysed with 6 N hydrochloric acid for 6 h. The main product was aspartic acid (peak D, yield 3.2%). Glycine (peak G, yield 0.8%) and alanine (peak H) were also found in the hydrolysate. The peak K corresponds to that of β -alanine (yield 0.7%). *f*, A, B, C, unknown; D, aspartic acid; E, glycine; G, alanine; H, buffer change; I, isoasparagine; J, β -alanine. Reaction conditions: electric current, 55 mA; reaction temperature, 5° C; reaction time, 3 h. The amino acids in the reaction mixture were analysed without hydrolysis (*f*). Asparagine (peak E, yield 1.1%) and isoasparagine (peak I) were formed by CGDE. A larger aspartic acid peak however (peak D, yield 2.6%), was found. This suggests that the CGDE process could hydrolyse the amide bond of the asparagine and isoasparagine formed. Glycine (peak F, yield 0.1%), alanine (peak G), and β -alanine (peak J) were also observed. The nature of the large peak B is not known; however, the peak B disappeared after acid hydrolysis (*g*). The yields of aspartic acid, glycine, alanine, and β -alanine after hydrolysis were 4.5, 0.5, 0.3, and 1.2%, respectively.

anodic compartment. In the amination reaction of carboxylic acid (0.0025 mol in 10 ml of concentrated aqueous ammonia), CGDE took place in conditions of ammonia gas saturation and stirring. All reactions were carried out at 1 atm. The reaction temperature was measured by thermometer in the reaction tube which was immersed in the methanol-dry ice bath. The applied electric current (d.c.) was 450–600 V and 20–100 mA. The reaction time ranged from 0.5–6 h. After the reaction ceased, the reaction mixtures were evaporated to dryness under reduced pressure and the residues were appropriately diluted for amino acid analysis. Some of the reaction products were hydrolysed with hydrochloric acid and the amino acids were then analysed. The reaction mixture was also treated with 2,4-dinitrofluorobenzene, and the resulting dinitrophenyl (DNP)-amino acids were separated by column chromatography and thin layer chromatography. The major amino acid products were confirmed as DNP-amino acids.

Figure 1 represents amino acid formation from acetic acid, propionic acid, succinic acid, glutaric acid, succinyl-anhydride, and succinimide. The resulting amino acids, their yields, and the reaction conditions are described. The yields of amino acids in some amination reactions reached up to 13% (Fig. 1b). These amino acid formations by CGDE do not, however, represent optimal conditions.

Facilitation of lysosome disruption by ATP at low pH

HAYASHI *et al.*¹ reported that ATP stimulates *in vitro* the degradation of proteins at pH 4.5 by lysosomes which were intact at the start of the experiment. In accordance with our previous results, no effect was found at pH 5.0 (ref. 2). Although they found more rapid degradation by disrupted lysosomes, these authors concluded that the effect of ATP was not due to an increased labilisation of the lysosomal membrane, but that "ATP facilitates the pinocytotic engulfment of proteins into lysosomes and thereby stimulates proteolysis". This conclusion was mainly based on experiments on non-sedimentable cathepsin D activity, discussed below. We have reinvestigated the effect of ATP on protein breakdown at different pH values, and found essentially the same results. Our evidence shows, however, that the increase of proteolysis is due to facilitation of lysosome disruption by ATP at pH 4.5.

Figure 1 shows the degradation of haemoglobin using intact

Fig. 1 Haemoglobin degradation by intact and disrupted lysosomes. A mitochondrial-lysosomal fraction was isolated from rat liver according to Sawant *et al.*³. The particle fraction was used either intact, or after disruption by three cycles of freezing in liquid nitrogen and thawing at 38°C. The incubation mixture contained 2.5 mg mitochondrial-lysosomal protein, 10.8 mg haemoglobin, 50 mM Na-acetate buffer and 0.25 M sucrose in a volume of 3.1 ml. The incubation temperature was 38°C. ATP and MgSO₄ were used at concentrations of 10 mM. At the times indicated, samples of 0.5 ml were added to 1.0 ml ice-cold 10% trichloroacetic acid. The mixture was cooled immediately and centrifuged at 0°C. Degradation products were determined in the supernatant by means of the Folin-Ciocalteu reagent, using tyrosine as standard⁴. ●, Intact lysosomes, no additions; ■, intact lysosomes, ATP and Mg²⁺ present; ○, disrupted lysosomes, no additions; □, disrupted lysosomes, ATP and Mg²⁺ present. Degradation at a, pH 4.48; b, pH 4.73; c, pH 5.05.

and disrupted mitochondrial-lysosomal fractions prepared according to Sawant *et al.*³. Similar results were obtained with a mitochondrial-lysosomal fraction prepared according to Bouma and Gruber⁵ and with a fraction isolated from hepatocytes⁶. ATP, in the presence of Mg²⁺ ions, stimulated the degradation of haemoglobin by the intact particle fraction at pH 4.48, but not at pH 4.73 and pH 5.05. During the first 30 min, the stimulation at pH 4.5 was two to three times in several experiments. The same results were obtained for the

Fig. 2 Hydrolysis of glycyl-phenylalanyl-*p*-nitroanilide by intact and disrupted lysosomes. The incubation conditions are the same as those described under Fig. 1, except for the inclusion of 10 mM NaCl, 9 mM dithiothreitol and 0.315 mM GPNA. The trichloroacetic acid supernatants were added to 0.2 ml 2.0 M Tris-HCl buffer pH 9.0, and the adsorbance was determined at 412 nm. ●, Intact lysosomes, no additions; ■, intact lysosomes, ATP and Mg²⁺ present; ○, disrupted lysosomes, no additions; □, disrupted lysosomes, ATP and Mg²⁺ present. Degradation at a, pH 4.45; b, pH 4.78; c, pH 5.00.

hydrolysis of glycyl-phenylalanyl-*p*-nitroanilide (GPNA), a low-molecular weight substrate of cathepsin C (ref. 7), as is shown in Fig. 2. These findings are most simply explained if one assumes that ATP facilitates the disruption of the lysosomal membrane at pH 4.5.

Hayashi *et al.*¹ rejected this explanation because ATP did not enhance the non-sedimentable cathepsin D activity. Non-sedimentable activity is, however, not always a valid reflection of lysosomal integrity⁸, since at low pH values some enzymes are strongly adsorbed to membranes of disrupted lysosomes⁹. For that reason, we investigated the effect of ATP on the 'free' activity of cathepsin C. The results are shown in Table 1. The presence of ATP clearly accelerates lysosomal disruption at pH 4.5 only. It should be noted, that at the times indicated in the Table, the cathepsin C assay, which itself lasted 15 min, was started. ATP was present in both incubation systems during

Table 1 Influence of ATP on the 'free' cathepsin C activity of a mitochondrial-lysosomal fraction during incubation at pH 4.5, 4.8, and 5.0

Time (min)	ATP	'Free' cathepsin C activity (%)					
		pH 4.48		pH 4.78		pH 5.00	
0	—	—	—	—	—	—	—
10	25	29	24	24	26	26	26
20	58	78	41	43	42	37	37
30	86	87	65	66	59	54	54
40	94	96	82	89	82	79	79
60	97	102	91	89	100	98	98

A mitochondrial-lysosomal fraction was prepared according to Sawant *et al.*³ and incubated as described under Fig. 1. At the times indicated, samples of 0.5 ml were added to 0.5 ml buffered isotonic GPNA solution (final concentrations: 50 mM sodium acetate buffer, 10 mM Cl⁻, 9 mM dithiothreitol, 0.315 mM GPNA and 0.25 M sucrose). The chloride ions and the thiol were added to activate and stabilise cathepsin C (ref. 10). To those samples which had been preincubated without ATP and MgSO₄, these substances were added together with the GPNA solution to give the same final concentration of 5 mM. After 15 min at 38°C, the incubation with GPNA was stopped by adding 0.2 ml trichloroacetic acid to a final concentration of 10%. The trichloroacetic acid supernatant was added to 0.2 ml 2M Tris-HCl buffer pH 9.0, and the absorbance was determined at 412 nm in 2 cm cells. Blanks were prepared by adding trichloroacetic acid before the enzyme. The 'free' cathepsin C activity, determined in this way, is expressed as a percentage of the value obtained after three cycles of freezing-thawing (see text under Fig. 1). Three representative experiments are shown; +, the presence of 10 mM ATP and 10 mM Mg²⁺; —, their absence during incubation.

the assay. Thus, the relative increase in lability at pH 4.5, due to the presence of ATP during the incubation, is larger than that indicated by the data of Table 1.

At pH 4.8 and 5.0 ATP has no effect on lysosomal membrane stability. At pH 7.0, ATP even stabilises the lysosomal membrane^{11,12}. Thus, the direction and the magnitude of the effect of ATP on the lysosomal membrane is strongly pH dependent.

This is reflected in the absence of a stimulating effect of ATP on the degradation of haemoglobin and GPNA at pH 4.75 and 5.0. The pH dependence explains why Hayashi *et al.*¹ found no effect on acid phosphatase and β -glucuronidase activity measured at pH 4.8 and 5.2 respectively.

The second argument of Hayashi *et al.*¹ for the hypothesis that ATP stimulated the uptake of macromolecules into lysosomes, was the finding that ATP increased the amount of non-washable cytosol protein in the mitochondrial-lysosomal pellet slightly. A control experiment with a disrupted fraction was, however, not carried out. We found that even at neutral pH adsorption of cytosol proteins was as good to a disrupted as to an intact mitochondrial-lysosomal fraction.

Thus the effects of ATP can be explained by its strongly pH-dependent influence on the stability of the lysosomal membrane. No valid evidence for the uptake of macromolecules into lysosomes at pH 4.5 exists.

We thank Miss Lineke Lanting and Miss Anneke Duursma for their technical assistance.

Inhibition of high-affinity glial uptake of ¹⁴C-glutamate by folate

EVIDENCE is accumulating to support the suggestion¹ that folic acid (pteroyl glutamic acid) may play a role in epileptic phenomena. *Grand mal* epileptic patients undergoing anti-convulsant drug therapy are likely to develop megaloblastic anaemia as a result of disturbances in folic acid metabolism¹, and it has been reported that correction of the folic acid deficiency by folate therapy results in an exacerbation of the frequency and intensity of epileptic episodes^{2,3}. It is also known that folate and related pteridines possess convulsant properties in their own right when administered in high intravenous doses to rats, or given intracortically⁴.

In a recent examination⁵ of the effects of iontophoretically applied folate or folinate (N⁵-formyl-5, 6, 7, 8-tetrahydro-folate) on the firing rate of neurones in the cat pericruciate cortex, these substances were found to have powerful facilitatory effects on the firing of spontaneously active, or glutamate-activated cells though they possessed only weak excitatory actions on quiescent neurones. The mechanism of the facilitatory action was not clear, but the authors provided some evidence for a possible blockade of inhibitory γ -aminobutyric acid (GABA) receptors. Similarly, it has been found that folate will antagonise presynaptic inhibition in the cuneate nucleus⁶; however, no antagonism of GABA-induced inhibition was demonstrable⁷.

Glutamate is likely to be an important excitatory neurotransmitter in the CNS⁸, and the major means of terminating the synaptic action of this amino acid is considered to be by re-uptake, largely into glial cells⁹. The rat dorsal root ganglion provides a convenient model system for studying the glial uptake of amino acids and has been previously used¹⁰ to demonstrate an active, energy-dependent, high-affinity transport process ($K_m = 2 \times 10^{-5}$ M) for glutamate.

Here I examine the possibility that folate might interfere with this glutamate uptake mechanism.

Rat dorsal root ganglia were isolated and desheathed, and transferred in pairs to 0.75 ml of Krebs-bicarbonate medium (pH 7.4) and preincubated for 10 min at 27°C under O₂–CO₂ (95 : 5). L-U-¹⁴C-glutamate (Amersham) was then added to give a final concentration of 10⁻⁶ M, and the incubation con-

tinued for a further 15 min. At the end of this time ganglia were rapidly rinsed in ice-cold Krebs medium, blotted on filter paper and weighed individually. The tissues were transferred to liquid scintillation vials, solubilised with 400 μ l Protosol (NEN Chemicals) and total radioactivity assayed by liquid scintillation counting. Uptake of ^{14}C -glutamate was found to be linear with time. In each series of experiments ganglia were included which were incubated throughout at 0°C . The radioactivity in these blanks, which enabled a correction to be made for the ^{14}C -glutamate localised in the extracellular water, and for uptake due to diffusion, was subtracted from the values in the corresponding experimental sample (in each case the radioactivity in the blanks was less than 16% of the control). ^{14}C -glutamate was accumulated by dorsal root ganglia at a rate of 5.86 ± 0.33 pmol per mg tissue per 15 min (means \pm s.e.m. of 10 independent observations).

The effects of folate (Sigma, UK), the related pteridine, folinate (calcium salt; Lederle) and the dihydrofolate reductase inhibitor, methotrexate, 4-amino- N^{10} -methylpteroyl glutamic acid (Lederle) were examined at a single test concentration of $5 \times 10^{-4}\text{M}$, on the uptake of 10^{-6}M ^{14}C -glutamate. Each of the three compounds tested produced an inhibition of $38.8 \pm 4.9\%$, $35.5 \pm 6.4\%$ and $27.2 \pm 1.9\%$ respectively (means \pm s.e.m. of eight independent observations).

The Michaelis-Menten kinetics were determined for folate, using a limited range of folate concentrations ($2.5 \times 10^{-4}\text{M}$ – 10^{-3}M). The values are presented as a Dixon plot (Fig. 1) which indicates that folate inhibits competitively the high-affinity uptake of ^{14}C -glutamate with a $K_i = 5.64 \times 10^{-4}\text{M}$.

The effects on the uptake process of a clinically useful anti-convulsant, diphenylhydantoin, were examined at a concentra-

tion of $5 \times 10^{-4}\text{M}$. The compound itself was without effect on the uptake of ^{14}C -glutamate, nor did it affect the inhibition of uptake by folate.

The significance of the inhibition of glutamate uptake by folate seen in these experiments, in relation to the epileptic seizure, and to the effects of the therapeutic administration of folate, is not clear. It seems unlikely that extracellular folate concentrations obtained following even prolonged therapy would be sufficient to markedly influence the re-uptake of glutamate from the synapse. But folate is largely localised in synaptosomal fractions¹¹, and it has been suggested¹² that focal epileptic discharges may result from an accumulation of folate in the extracellular space around the focus.

Presynaptic inhibition at mammalian peripheral synapse?

STIMULATION of sympathetic nerves leading to the intestine causes a reduction in intestinal motility¹. Norberg² showed that these nerves ramify mainly in the enteric plexuses and has suggested that inhibition may be exerted at a neural rather than at a muscular level but this suggestion has been disputed³. Neural inhibition has been shown to occur by the postsynaptic action of transmitter⁴ but at some synapses it has been established that transmission may be inhibited presynaptically⁵.

Here we describe experiments directly supporting Norberg's suggestion and which suggest that sympathetic inhibition of synaptic transmission in the myenteric plexus of the guinea pig may be mediated presynaptically rather than by the postsynaptic action of inhibitory transmitter.

Intracellular recordings were made from myenteric neurones in flaps of plexus attached to the anal end of an adjacent segment of guinea pig mid small intestine⁶. The periarterial nerves leading to the intestinal segment were drawn into a suction electrode and stimulated electrically. Synaptic activity was evoked in the myenteric plexus by use of a pair of fine platinum electrodes, one under and the other just above the plexus flap⁷. In some experiments synaptic activity was evoked by distending a balloon placed inside the lumen of the gut segment⁸. Preparations were bathed in modified Krebs solution maintained at 35°C ; atropine ($2 \times 10^{-7}\text{ g ml}^{-1}$) was present during each experiment to prevent cholinergic excitation of the smooth muscle⁹.

In most experiments, trains of 10–100 stimuli (pulse width 0.1 ms, frequency 0.1–50 Hz) applied to periarterial nerves

Fig. 1 Effect of periarterial nerve stimulation on transmission in the myenteric plexus of guinea pig small intestine. The upper trace in each illustration records the membrane potential of a myenteric neurone at slow scan speed (horizontal calibration 200 ms); the lower traces show EPSPs evoked by single transmural stimuli applied across the plexus flap close to the recording site (horizontal calibration 50 ms). In *a* and *c*, recorded respectively 15 s before and 15 s after *b*, it can be seen that such stimuli each evoked two EPSPs. But when the periarterial nerves leading to the plexus flap were stimulated (solid bar, 10 Hz for 1 s) just before a transmural stimulus (*b*) only a single EPSP was evoked. Vertical calibration bar (10 mV) applies to each trace.

produced no detectable change in the electrical properties of the myenteric neurones. Transmural stimulation of the flap of myenteric plexus never evoked inhibitory postsynaptic potentials; moreover Nishi and North⁸ have shown that noradrenaline, the presumptive transmitter released by periarterial nerves to the intestine, has no effect on the sensitivity of myenteric neurones to acetylcholine (ACh). In two out of more than 40 experiments, short trains of impulses (10 Hz for 1 s) applied to periarterial nerves caused a persistent discharge of excitatory postsynaptic potentials (EPSPs). Such EPSPs were identical to those that could be evoked by close transmural stimulation of a plexus flap and are presumably mediated by the release of ACh^{7,8}. We take this observation to support the view that periarterial nerves to the small intestine contain a small proportion of vagal parasympathetic fibres⁹.

An intermittent discharge of EPSPs was recorded from some neurones in the absence of any apparent stimulus⁶. Trains of stimuli (2 s duration, 5–10 Hz) applied to the periarterial nerves frequently caused either a reduction in the frequency of occurrence of EPSPs or totally abolished the discharge of EPSPs for several seconds (2–7 s). Distension of the intestinal segment by inflation of the intraluminal balloon increased the frequency of discharge of EPSPs or evoked a discharge of EPSPs in quiescent neurones. Such a discharge of EPSPs was reduced or abolished by a concomitant train of stimuli to the sympathetic nerve. These myenteric neurones mediate either inhi-

bition or excitation of adjacent smooth muscle layers¹⁰; evidently sympathetic nerve stimulation may depress transmission in both inhibitory and excitatory pathways.

Close transmural stimulation evoked a single EPSP or a cluster of EPSPs; a preceding train of stimuli applied to periarterial nerves either abolished the synaptic response or reduced the number EPSPs in the cluster. If the EPSPs were sufficiently synchronous to evoke an action potential, preceding sympathetic nerve stimulation reduced the synaptic response so that only subthreshold EPSPs were recorded. In some experiments, it was possible to evoke two EPSPs and to selectively abolish one of these by sympathetic nerve stimulation. Such an experiment is illustrated in Fig. 1. It can be seen that the second EPSP was abolished in an 'all-or-none' manner whilst the first EPSP was unaffected. In other experiments early EPSPs were abolished rather than late EPSPs. The scatter of latencies for EPSPs could result from delays due to transmission through interneurons but this seems unlikely as EPSPs were repeatedly evoked during repetitive transmural stimulation (10 Hz); polysynaptic nerve pathways in the myenteric plexus often failed to transmit at frequencies as low as 0.2 Mz (ref. 6).

When intracellular recordings were made from longitudinal or circular muscle, trains of stimuli (20 Hz for 5 s) applied to periarterial nerves produced no detectable change in membrane potential of cells of longitudinal layer. They did, however, produce a detectable hyperpolarisation (5–10 mV) of circular muscle membrane potential; frequencies less than 20 Hz only occasionally produced a small hyperpolarisation (1–3 mV) of this layer.

The simplest explanation for our findings is that sympathetic inhibition is mediated presynaptically. In most experiments repetitive sympathetic nerve stimulation reduced the number of EPSPs in a cluster of synaptic potentials. As the amplitude of the EPSPs which persisted during periarterial nerve stimulation was not reduced, it seems unlikely that inhibition is mediated by a conductance change in the postsynaptic membrane. The possibility that inhibition is mediated postsynaptically at restricted areas some distance from the cell soma, however, cannot be completely excluded. It would also seem from these experiments that the mechanism of sympathetic inhibition is somewhat different to that observed at the crayfish neuromuscular junction, as EPSPs were abolished in an 'all-or-none' manner rather than by a reduction in quantal content⁸. Nevertheless, these experiments show that sympathetic nerve stimulation may inhibit transmission in the myenteric plexus and may block local reflexes activated by distension of an intestinal segment.

Conductance increase by adrenaline in guinea pig taenia coli studied with voltage clamp method

Using the double sucrose gap method, Bülbring and Tomita² have shown that adrenaline hyperpolarises the membrane and reduces the electrotonic potential produced by constant current pulses in the guinea pig taenia coli muscle. They concluded, from the effects of membrane polarisation and changing external ionic composition on the adrenaline action, that an increase in the K and Cl conductances of the membrane is responsible for the hyperpolarisation.

This agrees with the results obtained from ionic flux experiments³. In contrast, however, it has been recently reported, on the basis of voltage clamp experiments, that adrenaline increases the negativity of the potassium equilibrium potential without causing significant changes in the membrane conductance⁴. As the voltage-current relation is roughly linear^{1,3,4}, it is difficult to reconcile these different conclusions.

We therefore examined the effect of adrenaline using the current clamp and voltage clamp methods in the same preparation. The double sucrose gap apparatus was essentially the same as that previously used², although of slightly smaller dimensions, that is, the centre pool where the test solution flowed, was 700 μm in width. The vertical amplifier of the oscilloscope (Textonix, 3A7) was used as a feedback amplifier for the voltage clamp experiments and electrical responses were recorded with a rectilinear pen recorder (Nihon Kohden, PMP-3004).

Figure 1 shows effects of adrenaline (10^{-6} g ml⁻¹) injected into the stream of Krebs solution flowing through the centre pool, in current clamp (Fig. 1a) and voltage clamp (Fig. 1b) conditions. In Fig. 1a, a hyperpolarising current pulse (2 s duration) of constant intensity (5×10^{-7} A) was applied every 8 s. The previous observation², that the membrane was hyperpolarised and the electrotonic potential was concomit-

Fig. 1 Effects of a short application of adrenaline (10^{-6} g ml⁻¹) on the guinea pig taenia coli. Adrenaline infusion is indicated by the horizontal bar. Top trace, membrane potential, downward deflection indicating hyperpolarisation; bottom trace, membrane current, downward deflection indicating inward current. *a*, Current clamp; *b*, voltage clamp.

Fig. 2 Effects of a prolonged application of adrenaline (B) and its recovery (C). Compare with control experiments (A). *a*, Current clamp; *b*, voltage clamp. Note decrease in electrotonic potential (top trace) in *a*, and increase in membrane current flowing during the voltage pulses (bottom trace) in *b* during adrenaline application. Also note that an early transient inward current produced by depolarising voltage pulse was abolished in B.

antly reduced by adrenaline, was confirmed. When adrenaline was applied in the voltage clamp condition, an outward current was observed and in response to hyperpolarising voltage pulses the membrane currents were increased (Fig. 1b). Thus, it is clear that adrenaline increases the membrane conductance and produces an outward current.

This was also confirmed by studying the current-voltage relationship (Fig. 2a) and the voltage-current relationship (Fig. 2b) in the absence and presence of adrenaline (5×10^{-7} g ml⁻¹). After taking control records in current clamp and voltage clamp conditions in normal Krebs solution, adrenaline was continuously administered and 10 min later the same experiments were repeated in the presence of adrenaline. Records were taken 10 min after washing out the adrenaline. There was some gradual recovery in membrane potential and membrane resistance during prolonged exposure to adrenaline, however, it was clear that the membrane was still hyperpolarised, the membrane resistance reduced, and the spike or the early transient inward current blocked. Thus, the results were similar to those obtained by a short application of adrenaline.

It was also demonstrated that the outward current produced by adrenaline was increased during conditioning depolarisation and reduced during conditioning hyperpolarisation. When the membrane potential was clamped at a hyperpolarised level of more than 15 mV beyond the resting potential, adrenaline produced an inward current.

Our results support the idea that adrenaline increases the membrane conductance, and hyperpolarises the membrane by increasing the outward current. As no careful examination was made of tail currents following repolarisation from a large depolarisation to different voltage levels, a shift in the potassium equilibrium potential is not ruled out by the present experiments. As far as the conductance change is concerned, however, our results conflict with the data obtained by Inomata and Kao⁴. The reason for their failure to demonstrate the conductance change by adrenaline is not clear.

Development of polycystic ovaries in rats actively immunised against T-3-BSA

THE aetiology of the polycystic ovary syndrome of Stein-Leventhal¹ is still unknown. Histologically, the ovaries from Stein-Leventhal patients are comparable in many respects to polycystic rat ovaries which have been observed in sexually mature rats following the administration of testosterone propionate during the neonatal period or continuous exposure of adult rats to a constant light environment². Furthermore, increased *in vitro* conversion of progesterone to androgen and oestrogen has been described in incubations of both human and rat polycystic ovaries³. A clear insight into altered ovarian physiology which may precede the development of polycystic ovaries in the rat might therefore provide a better understanding of the human syndrome.

Mahesh and Greenblatt⁴ have suggested that the Stein-Leventhal syndrome is caused by altered steroid synthesis in the ovary resulting in an imbalance of the pituitary-ovarian axis and subsequent persistent stimulation of the ovary by follicle stimulating hormone (FSH). A previous report from this laboratory has clearly shown that active immunisation of intact male rats against testosterone-3-(O-carboxymethyl) imino-bovine serum albumin (T-3-BSA) leads to a grossly elevated total serum testosterone concentration with a concomitant decrease in the circulating biologically active free testosterone fraction due to high-affinity binding by anti-testosterone antibodies^{5,6}. This situation was reflected in significantly increased serum concentrations of FSH and luteinising hormone (LH). These observations led us to postulate that a similar immunisation of female rats might induce gradual alterations in the endocrine status of the host conducive to the development of polycystic ovaries, thus providing a well controlled model in which aspects of the aetiology of the syndrome can be examined.

Adult female Sprague Dawley rats (18 weeks) used in this study were housed in an air-conditioned room illuminated between 0700 h and 1900 h. Only rats which had shown at least two consecutive 4-d oestrous cycles (determined by daily vaginal smears) were used. Seven experimental animals were immunised against a T-3-BSA conjugate prepared by the method of Erlanger *et al.*⁷. The immunogen (100 µg) was administered

as described previously⁵ at monthly intervals. Controls were immunised against unconjugated BSA. Fifteen weeks after beginning immunisation, vaginal smears were taken on 8 consecutive days. At this time all animals immunised against T-3-BSA exhibited persistent vaginal cornification whereas controls continued to cycle normally. After 17 weeks, all animals were exsanguinated, serum collected⁵ and the ovaries removed and fixed in Bouin's solution. Significant serum antitestosterone antibody titre (greater than 1:20 final dilution)⁵ was detected in three of the T-3-BSA immunised animals, ranging between 1:200–1:700. Ovaries removed from these animals bore massive fluid-filled cysts up to 1.5 cm diameter. Following fixation and dehydration the ovaries removed at autopsy were embedded in paraffin wax and serial 5 µm sections cut and stained with haematoxylin and eosin. Microscopic examination of sections from control ovaries (Fig. 1a) revealed apparently normal follicular development with abundant corpora lutea. Those from animals which produced anti-T-3-BSA antibodies, however, displayed large distended follicular cysts characterised by almost total absence of a granulosa cell layer; corpora lutea were rarely observed (Fig. 1b).

Fig. 1 Photomicrographs of follicles present in, a, ovary removed from a control rat immunised against BSA; b, ovary removed from a rat immunised against T-3-BSA. F, Normal follicle; CF, cystic follicle; CL, corpus luteum.

The total serum testosterone concentration in these animals, as determined by radioimmunoassay⁸ was significantly higher than in controls (Table 1), but using an equilibrium dialysis technique described previously⁵, the circulating biologically active⁹ free testosterone fraction was found to be significantly reduced (Table 1). Serum concentrations of immunoreactive LH, FSH and prolactin were each determined by radioimmunoassay as before⁵ and the values obtained are shown in Table 1. While experimental FSH values were significantly elevated neither LH nor prolactin differed from controls.

These data indicate that a reduction in the circulating free

testosterone fraction which occurs in animals immunised against T-3-BSA is reflected in a selectively increased pituitary FSH output which might be a factor in the aetiology of pathological changes observed in the ovaries of animals thus treated. A detailed examination of various parameters of ovarian physiology before the appearance of polycystic ovaries in such animals may be of value in our understanding of the human syndrome.

We thank the Tenovus Organisation for continuing generous financial support and to the Rat Pituitary Hormone Distribution Program of the National Institute of Arthritis, Metabolism and Digestive Diseases, National Institute of Health, Bethesda, Maryland for the kits which enabled us to measure the rat LH, FSH and prolactin. We also thank Professor K. Griffiths for criticism and advice. This report forms part of a thesis presented by S. G. H. for the degree of PhD in the University of Wales.

Influence of NAD⁺ on development of mouse blastocysts *in vitro*

THE metabolites pyruvate and lactate are of central importance for the development of preimplanted mouse embryos¹. One-cell ova cannot develop when lactate is the only energy source², but the necessary pyruvate can apparently be provided for the first cleavage division when the incubation medium contains NAD⁺ as well as lactate³. Cross and Brinster have reported that the development of the mouse embryo was optimal after the first cleavage division when both lactate and pyruvate were present in the medium⁴. Recent biochemical investigations have demonstrated that NAD⁺ metabolism can interfere with DNA synthesis: this effect is independent of the function of NAD⁺ as a coenzyme of dehydrogenases^{5,6}. We have investigated whether NAD⁺ supports the development of mouse blastocysts from the two-cell stage embryos by converting lactate to pyruvate, or whether it inhibits this development by interfering with DNA synthesis. •

Sexually mature virgin female white inbred mice (8–10 weeks old) were mated for 2–3 h with sexually mature males of the same strain (two females per cage). Females with vaginal plugs were segregated, and the embryos were obtained from these animals 28–30 h later by flushing Culture Medium BMOC-2 (ref. 7) through the oviduct. The embryos were kept during the collecting period in Culture Medium

Table 1 Effects of NAD⁺ on development and NADH content of two-cell embryos

NAD ⁺ (mM)	Development to blastocyst stage (%)		NADH (mM)*
	BMOC-2(+pyruvate)	BMOC-2(-pyruvate)	
0	92 (178†)	40 (35)	0
0.23	65 (26)	81 (21)	0.005
1.0	52 (71)	24 (29)	0.04
5.0	28 (50)	10 (20)	0.12

* Concentration after 66 h incubation with BMOC-2 (without pyruvate) with various NAD⁺ concentrations.

† Numbers of embryos.

BMOC-2 with lactate and pyruvate at 30–35° C; afterwards they were washed twice with 0.9% NaCl and 0.1% Ficoll (Pharmacia, Sweden) and transferred to 100 μ l Culture Medium BMOC-2 which contained lactate or lactate and pyruvate. The medium also contained NAD⁺ in various concentrations and was overlaid with silicone oil Tegiloxan 50 (Goldschmidt, Essen) for the cultivation period. The embryos were cultivated essentially as described by Brinster⁷.

NAD⁺ and NADH were measured with alcohol dehydrogenase and lactate dehydrogenase⁸ by fluorescence spectrometry (Zeiss ZFM 4C).

As seen from Table 1 optimal development of the mouse embryos was obtained using the complete Culture Medium BMOC-2 which contained 0.25 mM pyruvate. After 66 h incubation, 92% of the embryos isolated at the two-cell stage had developed to blastocysts but when pyruvate was omitted this rate was only 40%. In medium containing pyruvate, even small NAD⁺ concentrations inhibited embryonic development (Table 1). With increasing NAD⁺ concentrations this inhibition became stronger and no blastocysts were observed when the culture medium contained 12.5 mM NAD⁺.

But, for embryos cultured without pyruvate, development was stimulated by low NAD⁺ concentrations (Table 1). With higher NAD⁺ levels (1 mM and higher) the formation of blastocysts from the two-cell stage embryos was inhibited as in the pyruvate-containing medium. No development to blastocysts was observed with a NAD⁺ concentration of 12.5 mM in the culture medium.

Table 1 also shows that the NADH content of the culture medium at the end of an incubation without pyruvate is dependent on the NAD⁺ concentration. The measured NADH concentration increased almost proportionally with the NAD⁺ concentration in the investigated range although we can say nothing about the turnover of the NADH. These data clearly demonstrate that lactate can be metabolised to pyruvate under these conditions. We do not know, however, where these reactions could occur: by intracellular dehydrogenases, by dehydrogenases attached to the zona pellucida, or by dehydrogenases released from the embryos into the medium. This is especially problematical since the pyridine nucleotides cannot usually penetrate mammalian cell membranes⁹.

Under our experimental conditions the NAD⁺ as a coenzyme of dehydrogenases can apparently provide the pyruvate which the embryos require for their development. But, with higher NAD⁺ concentrations the second metabolic effect of NAD⁺ overcomes this stimulation and its inhibitory effect on proliferation becomes predominant.

This inhibitory effect may be connected with the formation of adenosine diphosphoribose (ADPR)⁴ and its polymer and with the binding of ADPR to the chromatin^{5,6}. An NAD glycohydrolase (EC 3.2.2.5) activity is found in the preimplanted mouse embryo¹⁰ which could be of significance in this connection. It is also possible that metabolic breakdown products of NAD⁺ are responsible for the inhibitory effect. Adenosine is found to act in this way on the development of the mouse embryo (unpublished results). Nolde and Hilz¹¹ reported that adenosine caused a reduction

in the proliferation of HeLa cells. We are investigating these problems and that of the uptake and metabolism of NAD⁺ by the embryo.

Evidence for sexual fusion and recombination in the dinoflagellate *Cryptocodinium (Gyrodinium) cohnii*

SEVERAL cytological and biochemical features of dinoflagellate chromosomes, such as low histone content^{1–3}, threadlike appearance under the electron microscope^{1,4–6}, absence of centromeres⁶, the condensed state persisting throughout interphase^{1,4–6}, unusual DNA⁷ and the controversial possibility of multistrandedness^{8,9}, suggest that the genetics of these organisms might be unusual. We report here initial experiments on the genetics of the heterotrophic marine, coccoid dinoflagellate *Cryptocodinium cohnii*¹⁰ previously believed to be asexual¹⁰. We have evidence of sexuality, complementation, recombination and a complex life cycle.

Axenic cultures of Puerto Rican and Woods Hole strains of *C. cohnii* (gifts from Drs K. Gold and L. Provasoli, respectively) and a strain which we isolated from Mattapoisett Bay, Massachusetts, were cloned by isolating single cells on agar by micromanipulation. Several clones of each strain were maintained on Gold's medium (GM)¹¹, either liquid or solidified with agar (1.0–1.5%).

We found that growing cultures have, in addition to reproductive cysts and coccoid individuals of many sizes and stages of development, motile flagellated cells—swarmers—of various sizes⁸ (Fig. 1a). DNA content per nucleus, also varies widely (Fig. 1b) as previously reported briefly, but within one cyst, the two, four or eight nuclei appear to contain equal amounts. Cysts with eight nuclei are rare and have minimal amounts of DNA per nucleus. Cysts with four nuclei also usually contain the minimal amounts while nuclei of binucleate cysts contain either minimal DNA or twice this amount. These results agree with present and previous observations^{10,11} of cysts producing one, two, four or eight cells. An average of such widely divergent amounts of DNA, as determined chemically^{3,8} is obviously too large if used to indicate a basal DNA content per genome. As we show later, cells of different size and DNA content result, at least in some cases, from cell fusion.

Fig. 1 *a*, Distributions in size of swimming cells of three representative cultures of *C. cohnii*, fm 1 mutant: ■, cells from bottom of log phase liquid culture; ●, cells from top of same culture; ▲, cells from bottom of stationary phase culture. *b*, Measurements of relative amounts of Feulgen dye bound to individual nuclei. A Leitz microspectrophotometer and the two wave length method^{14,15} for eliminating distributional error were used. □, Cells of wild type in log phase; ■, in stationary phase; ▨, nuclei of different reproductive cysts containing two, four, and eight nuclei.

We used easily distinguishable motility mutants for microscopy and for genetic experiments; one mutant occurred spontaneously and the other was isolated after ultraviolet irradiation. Following *Chlamydomonas* nomenclature^{16,17}, they were designated fm 1 and fm 2. Motile cells of fm 1 swim at a rate of 50 μm s⁻¹, about one-fifth the normal speed. The swarmers of fm 2 have flagella that appear normal under the light microscope, but locomotion is negligible, with most cells twitching only occasionally.

Extended microscopy of individual normal cells of *C. cohnii* is hampered by their speed. Examination of cultures of fm 1, however, especially cells from the bottom of log phase cultures, revealed motile cells adhering in pairs, moving characteristically with two nonsynchronously beating trailing flagella. (C. K. Franker has observed pairing in other cultures of *C. cohnii*.) With this slow moving strain, it was possible to photograph the pairing of cells and their gradual fusion into a single cell indistinguishable, except for two trailing flagella, from a normal individual of about double the size. (Similar behaviour has been described in other dinoflagellates¹⁸.) Figure 2 shows typical sequences for cells (gametes) of different sizes. Usually fusions involved cells of the same size, but occasionally cells of different sizes fused (Fig. 2*m*, *n* and *s*), and very rarely more than two cells fused. Smaller individuals usually paired side by side, commonly followed by a cruciform juxtaposition of the cells (Fig. 2*a* and *b*). Larger cells frequently completed the process end to end (Fig. 2*j*, *k* and *i*). Fusing cells, watched on open wet mounts until they dried on the glass, and then stained, showed that nuclear fusion closely follows that of the cytoplasm (Fig. 2*q*, *r* and *s*).

Examination of normal cells of *C. cohnii* also revealed pairing and fusion in all clones observed, including those of the Puerto Rican, Mattapoisett and McLaughlin strains. Since all clones represent single cell isolates, it seems likely that the sexuality of *C. cohnii* does not depend on different mating types (homothallism).

In genetic experiments cells of fm 1 were mixed with cells of fm 2 in liquid cultures. After about 10 h normally swimming cells were observed. This was remarkable since mutant cells have never reverted in culture for more than 400 generations, and, since they grow less vigorously than wild type, they would probably soon be overgrown by a back mutation. Fusion of an fm 1 cell and an fm 2 cell could be observed since the trailing flagellum of each could be recognised: that of fm 1 appeared to push both cells while that of fm 2 was ineffectual. Control

Fig. 2 Pairs of flagellated cells of *C. cohnii*, mutant fm 1. Magnification for living cells, $\times 528$; Feulgen-stained, $\times 1190$. a-e, Small cells (length about $14\ \mu\text{m}$) total time about 35 min; f-i larger cells (about $18\ \mu\text{m}$), total time about 90 min; j-l, large cells (about $23\ \mu\text{m}$), total time more than 12 h; m and n, anisogamous fusion; o, fusions of different sizes occurring at the same time; p, fusion product of largest size (about $32\ \mu\text{m}$); q, Feulgen-fast green-stained pair corresponding to (a) or (f); r, similarly stained fusion product corresponding to (e) or (i); s, anisogamous fusion corresponding to (r).

experiments in which cells of each mutant were incubated in culture filtrates of the other indicated that no diffusible substance was involved.

In mixtures of fm 1 and fm 2 some normally motile large cells appeared after 6 h, apparently too soon for completion of fusion, encystment, cell division and release of progeny, and we believe that they represent complementation in the 'zygote' itself. Since many fusions are complete within 1 h, the 6 h delay of restored function suggests that complementarily deficient organelles are not contributed by the 'gametes', but that new organelles are elaborated by the 'zygote'. Since cysts can give rise to single motile products, the 'zygote' might encyst for a time during which complementation is effected, after which it emerges as a normally swimming cell. Similar encystment of zygotes has been reported for other dinoflagellates¹⁸.

Only after a minimum of 14 h were the smallest rapidly swimming cells seen in the mixtures. These were too small to be the immediate products of fusion and are thought to be the products of reproductive cysts in which recombinational events occurred. This view is supported by the following genetic evidence. Early appearing large, fast swimming cells ('zygotes') were isolated by micromanipulation on agar. These soon rounded up, grew and ultimately produced four or eight progeny. These were in turn isolated and transferred to liquid medium. After several generations the cells were classified as to their type of motility and their ability to generate normal swimmers in mixtures with their parents (back crosses). Several types of segregations ('tetrads') were observed: in

fourteen zygotes analysed four contained only parental mutant types, four showed recombination—each contained two normal swimmers and two double mutants—and the rest appeared to yield parental types phenotypically, but each segregant showed recombination either with both or with neither parent. All segregants have been maintained for many generations in culture without alteration of phenotype, indicating the absence of 'post-meiotic' segregation.

The fact that the mutant characteristics are recoverable from complementing fusion products is consistent with Mendelism, as is the occurrence of normal recombinants with their double mutant counterpart. However the absence of tetrads showing four types of cells—parental and recombinant—is unusual, and suggests that recombination occurs before chromosome replication.

Our evidence indicates: (1) unusual homothallic sexuality with 'gametes' and 'zygotes' in a wide range of sizes, DNA content and chromosome numbers; (2) complementation in 'zygotes' after the fusion of two different mutants; (3) reduction in the first one or two divisions of the complementing 'zygote'; (4) that these reduction division(s) produce either: (a) both parental mutant types, (b) recombinants, both normal and double mutant, or (c) apparent parental types that display unexpected behaviour. These findings suggest that the chromosomes of this organism are functionally unineme, as has been proposed⁹ but that they behave unconventionally in several respects.

Aetiology of Down's syndrome inferred by Waardenburg in 1932

It is not widely known, and should be of historical interest, that in 1932 P. J. Waardenburg¹ suggested, in a monograph on the human eye, that Down's syndrome resulted from a chromosomal aberration due to non-disjunction. This was 5 yr after the first report of a chromosomal aberration in a mammal². In 1952, Mittwoch³ reported studying the meiotic chromosomes of a mongoloid patient and judged them to be normal. Waarden-

burg's suggestion was rarely cited, and the eventual discovery of trisomy-21 in 1959 (ref. 4) was generally received with surprise.

The relevant passage in Waardenburg's book appeared on pages 47 and 48 near the end of a chapter on mongolism. After enumerating the possible aberrations in several sentences, he went on to discuss the significance of the hypothesis for human genetics. He began as follows:

"Ich möchte die Zytologen anregen zu untersuchen ob es nicht möglich wäre, dass hier beim Menschen ein Beispiel einer bestimmten Chromosomenaberration vorläge. . . . Man sollte einmal beim Mongolismus untersuchen ob hier vielleicht 'chromosomal deficiency' durch 'non-disjunction' oder das umgekehrte 'chromosomal duplication' vorliegt."

(I should like to suggest that the cytologists investigate the possibility that we have here in man an example of a specific chromosomal aberration. . . . Mongolism should be studied to determine whether there may be a 'chromosomal deficiency' resulting from 'non-disjunction' or the converse, a 'chromosomal duplication'.)

Waardenburg is a Dutch ophthalmologist, formerly a practitioner in Arnhem and Lecturer in Medical Genetics at the universities of Utrecht and Leiden. He is now retired in Oosterbeek.

Electrophysiological evidence for colour channels in human pattern vision

LIGHT striking the eye is absorbed by three types of pigment preferentially sensitive to either red, green or blue light. The resulting neurophysiological signals are ultimately pooled before they activate the neural mechanism that underlies the perception of photometric brightness. On the other hand, the role of colour might be different when viewing coloured scenes containing fine detail (pattern vision) compared with standard photometric stimulus fields; colour signals may not be pooled as when perceiving brightness^{1,2}. There is evidence that the human visual system handles red patterns in parallel with green and blue patterns^{1,2}. I have attempted to determine spectral sensitivity curves for the red-sensitive and green-sensitive channels of human pattern vision. This was done objectively by measuring brain activity electrophysiologically.

When a subject viewed a pattern of red and black checks that exchanged places seven times per second, the visual area of the brain generated a 7 Hz alternating electrical waveform called an evoked potential (EP). Superposed on the red pattern was an unpatterned disk of desensitising light whose wavelength was λ . Evoked potential amplitude was progressively reduced by increasing the intensity of the superposed disk of light. The principle of this experiment was to compare disks of different wavelengths in their ability to attenuate EPs produced by the red pattern.

The intensity of the disk was logarithmically increased with time for 28 s and then abruptly restored to its initial value. The total intensity change was 1.9 log units. While the disk intensity was slowly changing, the red pattern,

which was oscillating at 7 Hz, was continuously eliciting EPs whose moment-to-moment amplitudes were recorded as a function of time.

This was done by a Fourier analyser that operated as a narrow-band EEG filter centred on 7 Hz; its output was the running average of the EP amplitude³. In this way a plot of EP amplitude against disk intensity was directly obtained over the 28 s stimulus period⁴. Irregularities were reduced by electronically averaging four such samples of the required plot, allowing 20 s rest between each sampling. The technical details and experimental advantages of this new rapid technique are discussed elsewhere^{4,5}.

Figure 1 shows how the amplitudes of the red pattern's EPs were altered by increasing the intensity of the superposed disk of light. It should be noted that identical red stimulus patterns elicited all the EPs shown in this figure. Only the superposed unpatterned disk of light differed. Figure 1 also shows that as the desensitising disk's intensity was increased, EP amplitude was at first unaffected or even rose a little and then decreased roughly proportionally to log intensity. These two regions were separated by a 'knee' that was often clearly defined (Fig. 1 arrows). The trace marked *a* shows the noise level; it was recorded with the red pattern occluded. The evoked potential amplitude fell to noise level at an intensity close to that for which the pattern disappeared. These last findings are similar to the results of changing stimulus contrast at constant intensity^{2,6-8}.

Curves such as those of Fig. 1 were similar in their main features whatever the colour of the desensitising light; thus, to a first approximation, the only effect caused by changing the disk's colour was to displace the plot bodily along the intensity axis. This indicated that the EPs produced by the red pattern could, in the first instance, be treated as though the differently-coloured disks of desensitising light would have identical effects when appropriately balanced for intensity.

Fig. 1 Effect of desensitising light on evoked potentials elicited by a red checkerboard pattern that oscillated at 7 Hz. The $2^\circ \times 2^\circ$ pattern of 676 nm, 9 min checks was viewed centrally. Ordinates: amplitude of pattern evoked potentials. Superposed on the pattern was a 6° patch of desensitising light. Intensities of desensitising light are plotted along abscissa for desensitising wavelengths of 452 nm, 561 nm, 580 nm and 619 nm. Four samples averaged for each plot. *a*, The noise level recorded with the red pattern occluded. *b*, Mean noise level. Arrows indicate positions of 'knees'. The time axes show, for each separate plot, the timecourse with which the desensitising light's intensity was changed. Half-widths of filters were 10 nm. Bipolar recordings between electrodes on theinion and 9 cm anterior along the midline. The left mastoid was grounded.

The spectral sensitivity of the red pattern EPs was found as follows: Clearly, the red pattern EPs were most sensitive to the wavelength which gave a plot at the extreme left hand side of Fig. 1. This was not, as might be supposed, when the pattern and disk had the same wavelength (676 nm); in fact the plot was shifted most to the left when the disk's wavelength was approximately 590 nm. The 590 nm curve was arbitrarily taken as reference. Some other curve (501 nm) was then shifted to the left by an amount I_{501} log units until the linear portion from the 'knee' downwards coincided with the corresponding part of the 590 nm curve. The relative sensitivity of the red pattern EPs to light of wavelength 501 nm, was then directly calculated from I_{501} . This procedure was repeated for all disk wavelengths. The filled circles in Fig. 2a plot relative spectral sensitivity against disk wavelength λ . Similar results were obtained by the criterion response method using evoked potential feedback²; these have been added in Fig. 2a. Peak sensitivity lies between 580–600 nm.

The range of desensitising intensities for which this spectral sensitivity curve applied was calculated as follows. When the wavelengths of the disk and of the pattern were the same (676 nm), the 'knee' was found to mark the point where the disk intensity was approximately the same as that of the pattern's bright checks (that is stimulus contrast was 33%). As mentioned above, spectral sensitivity was estimated for the sections of the plots of Fig. 1 that lay between the 'knee' and the lowest EP amplitude. Thus, the spectral sensitivity curve of Fig. 2 held from the 'knee' (where only little desensitising light had been added so that chromatic adaptation was slight) to an adapting level roughly 1.5 log units higher, where the red pattern could no longer be seen.

This use of the 'knees' illustrates how evoked potential recording can offer the possibility of quantitatively studying visual processes at everyday suprathreshold levels of sensation where available psychophysical methods may be uncertain or ineffective.

The dotted line in Fig. 2a shows the relative spectral sensitivity curve for luminance (brightness) perception measured by the method of heterochromatic flicker photometry. A $2^\circ \times 2^\circ$ unpatterned patch of wavelength 676 nm and 122 trolands was flickered against a comparison patch of wavelength λ . There was a $36^\circ \times 36^\circ$ white surround of 250 trolands. I have previously reported that this luminosity curve agrees closely with the spectral sensitivity curve of EPs elicited by rapidly flickering a spatially-unpatterned patch of light⁹. On the other hand, Fig. 2a shows that the dotted luminosity curve is quite different from the spectral sensitivity curve for red pattern EPs. The luminosity curve peaks near 555 nm. In contrast, the sensitivity of red pattern EPs is displaced markedly towards the red end of the spectrum, and peaks at 580–600 nm. This means that for pattern EPs, visual effectiveness is not directly proportional to luminance; for example Fig. 2a shows that red and green lights that were equally effective for the red pattern channel might differ in luminance by 0.5 log units.

Figure 2b shows the result of repeating these EP experiments, but with the red pattern replaced by a green (544 nm) pattern. When Fig. 2b and 2a are compared, it is clear that the green pattern's spectral sensitivity curve peaked at much shorter wavelengths (540–560 nm) than the red pattern's curve. The wavelength of the green peak was also estimated by fitting a displaced rod sensitivity curve to the data of Fig. 2b after allowing for prereceptor absorption¹⁰. The rod curve fitted quite well with its peak displaced to 530–540 nm. The green pattern peaked at roughly the same wavelength, or even at a lower wavelength, than the luminosity curve (Fig. 2a, dotted).

To what extent do the EP curves of Fig. 2 represent the action spectra of red-sensitive and green-sensitive channels in pattern vision? Isolation of colour channels

Fig. 2 a, —, The relative spectral sensitivity for brain potentials evoked by a red (676 nm) pattern; ●, individual points; . . . , relative luminosities of spectral lights determined by heterochromatic flicker photometry. b, As for a except that the pattern was green (544 nm).

is notoriously difficult, as the action spectra of different photopigments overlap. Thus, even if each colour channel subserving pattern vision were fed exclusively by a single type of photoreceptor, then even monochromatic lights would stimulate all channels to some extent. In the present case the blue-sensitive pigment was most probably unimportant, not only because its spectral sensitivity is well separated from the red and green-sensitive pigments, but also because a fine stimulus pattern was used (9 min checks). It is well known that the spatial resolving power of the blue-sensitive visual mechanism is coarse¹¹. The shapes of the spectral sensitivity curves were consistent with some minor contribution from green receptors in Fig. 2a and some minor contribution from red receptors in Fig. 2b. Furthermore, the EP curves of Fig. 2 peak at wavelengths that agree with estimates for the peak sensitivities of the red and green photopigments^{12,13} or colour mechanisms¹⁴⁻¹⁹. All this indicates that Fig. 2b to a fair extent represents the action spectrum of the green photopigment and that Fig. 2a describes, though with rather less precision, that of the red pigment.

The data reported above extend the findings of previous experiments in which subjects viewed an equiluminant pattern of adjacent red and green checks (or bars). Large pattern-specific EPs were recorded each time that the

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, '**Molecular Biology Comes of Age**' looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'**Molecular Biology Comes of Age**' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of '**Molecular Biology Comes of Age**' are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

red and green checks (or bars) exchanged places^{2,7,20,21}. I pointed out that such EPs could not exist unless red and green signals were still to some extent segregated on arrival at pattern-sensitive neurones^{2,7}. Furthermore, chromatic segregation might even be complete²¹. This explanation would also be consistent with the McCollough effect¹ and with evidence that lateral interaction occurs within each class of cone²²⁻²⁴. It is important, however, to distinguish this suggestion from the colour segregation observed when monochromatic patterns stimulate the chromatically-adapted eye (for example, as above and in ref. 22). The latter conditions would reveal peripherally-determined red, green and blue colour channels even if colour signals were no longer segregated when they reached pattern-sensitive neurones.

I thank Dr F. W. Campbell, Dr H. Spekrijse, and Professor R. A. Weale for their comments; Robert E. Cartwright for invaluable technical assistance; H. Wardell and workshop staff for constructing equipment; and the Medical Research Council for supporting this work.

Prehistoric human activity and blanket peat initiation on Exmoor

It now seems that the shallow tracts of peat which are so abundant in western parts of the British Isles began their development at about the time when the first signs of human activity became evident in the pollen record^{1,2} contained in the peat. These blanket mire complexes or "Terrainbedeckende Moore"³ have received relatively little attention from palaeoecologists and radiocarbon-dated pollen profiles are few; those which exist refer mainly to deposits from Ireland^{4,5} and the Southern Pennines^{6,7}. We now present a radiocarbon-dated pollen diagram, from a blanket mire on Exmoor, Somerset, which throws further light on the coincidence of prehistoric human activity and the initiation of blanket peat formation.

The deepest blanket mires found on Exmoor were on an upland plateau site termed The Chains. A monolith of peat from the mire was excavated and this was used both for palynological work and for radiocarbon dating. Pretreatment of the samples for dating was carried out according to the specification of the Palaeoecology Laboratory, Belfast, where the dating was performed. In effect this pretreatment involved the extraction of the fine particulate matter from the peat by a process of KOH digestion followed by sieving. The dated material thus consisted largely of pollen and spores together with fine fragments of fungal origin. Contaminant root material penetrating the profile from above was thus eliminated.

Selected results of pollen analysis together with the radiocarbon dates are shown in Figs 1 and 2. The diagram has been zoned on the basis of the characteristics of the pollen assemblage (see Table 1); in Table 1 the probable corresponding archaeological or historical period is also suggested.

The diagram bears a strong similarity to those published from mid-Wales⁸ and the Southern Pennines⁷. The dating of the basal layers at about the time of the arrival of farming cultures lends further support to the suggestion that the introduction of grazing animals² or the ploughing of marginal land⁹ may have assisted in the initiation of these deposits.

Shallow blanket peats of about 1 m in depth are more

Table 1 The Chains pollen zones and their interpretation

Pollen Zone	Major characteristics	Interpretation and date (radiocarbon yr)
EC1	Relatively high <i>Ulmus</i> and <i>Pinus</i>	Undisturbed woodland before arrival of farming cultures
EC2	Decline in <i>Pinus</i> and <i>Ulmus</i> . Increase in <i>Alnus</i> at the expense of <i>Quercus</i> . Increase in <i>Pteridium</i> ; <i>Plantago lanceolata</i> is consistently present	Arrival of farming cultures and the response of the woodland to their activities. Extrapolation from dates, assuming an even rate of peat formation suggests the period covers about 5,000-3,800 b.p. (Neolithic)
EC3	Gradual recovery in <i>Ulmus</i> to a maximum at end of zone. No recovery in <i>Pinus</i> . <i>Plantago</i> sporadic and <i>Pteridium</i> erratic	An unsettled period with no permanent human settlements. Dates between about 3,800 and 2,300 b.p. (Bronze Age)
EC4	Abrupt decline in <i>Ulmus</i> and increase in <i>Betula</i> , <i>Pteridium</i> and <i>Plantago</i> . A decline in <i>Tilia</i> precedes that of <i>Ulmus</i>	Increased activity in terms of farming, woodland clearance and settlement. Dates, about 2,300-1,500 b.p. (Iron Age-Roman)
EC5	A sudden decline in <i>Pteridium</i> and <i>Plantago</i> . An increase in <i>Betula</i>	Reduced human activity. Period begins at about 1,500 b.p. (end of Roman), but is of uncertain duration
EC6	Gradual rise in <i>Pteridium</i> and <i>Plantago</i> to a maximum at the end of the zone. Decrease in <i>Alnus</i> , rise in <i>Ulmus</i> and <i>Pinus</i>	Increased settlement and deforestation, especially of lowlands and valleys. Uncertain date, but possibly culminating in the Napoleonic Wars, about 150 yr ago
EC7	Decrease in <i>Pteridium</i> and <i>Plantago</i> . <i>Pinus</i> reaches maximum	Reduced intensity of farming. Possibly past 150 yr

Fig. 1 Selected pollen data and radiocarbon dates from the peat profile at The Chains, Exmoor. (% Arboreal pollen)

Fig. 2 Further pollen data from The Chains, Exmoor.

Fig. 3 Selected pollen data from the peat profile at Hoar Tor, Exmoor. (% Arboreal pollen)

common on Exmoor than are deep peats. Figure 3 shows a pollen diagram from a profile of one of these sites at Hoar Tor. Once again there is an *Ulmus* decline close to the base of the diagram, but the other features of the contemporary pollen assemblage, for example, low *Pinus* and high *Tilia*, suggest that this fall in elm corresponds to the second (zone EC4) *Ulmus* decline of The Chains diagram. This would mean that EHT3 = EC4 (Iron Age–Roman); EHT4 = EC5 (? Dark Ages); EHT5 = EC6 (Mediaeval–Napoleonic Wars); EHT6 = EC7 (past 150 y). The absence of radiocarbon dates makes it impossible to confirm these tentative correlations.

It has been pointed out² that the basal peats of blanket mires often contain evidence of human activity. The data reported here endorse that statement but also provide the basis for its qualification. The human activity recorded in the basal peats may date back to Neolithic times (for example, The Chains), or it may represent a more recent interference (for example, Hoar Tor). On Exmoor there are peats which began their formation at both of the major interference periods.

Moore² has suggested that stock grazing in a woodland under climatic and soil nutrient stress (caused by deteriorating climate and prolonged leaching respectively) could reduce regeneration and thereby tip the ecological balance in the favour of peat formation. Mitchell⁹ has described situations in western Ireland where Neolithic ploughing may have assisted the process of podsolisation by liberating iron in the upper soil layers which becomes deposited as a pan beneath the level reached by the plough. Once again the outcome is nutrient depletion and incipient blanket

peat formation. In the Exmoor context we favour the former explanation of how man may have influenced the course of peat initiation. The role of climate in this process must be emphasised. We postulate that man, or his domesticated animals, provided a final stress on an ecosystem already under climatic strain. It is salutary to note that both of the periods of blanket peat initiation on Exmoor correspond to times of deteriorating climate¹⁰.

We thank the Royal Society for grants towards the cost of equipment and radiocarbon dating.

matters arising

Singing muscles in a katydid

SIR,—Your Insect Physiology Correspondent¹ has perpetrated a common error by stating that the tymbal muscles of cicadas may contract at 4,500 Hz. The song of cicadas, like other types of insect, consists of pulses of sound. The sound frequency, which is controlled by resonance of the abdominal air cavities, was measured by me as 4,500 Hz in some large cicadas in Ceylon, but is considerably higher in small species. The pulse modulation frequency, which may relate to the contraction frequency of the tymbal muscles, has never been observed higher than about 600 Hz, even in species with a myogenic contractile mechanism.

Neither your correspondent, nor Josephson in the article quoted² mention that high contraction frequencies in neurogenic muscles have been measured not only in insects but also in some vertebrate muscles producing only a small output of energy (the cricothyroid muscle of the bat³; and a fish swim-bladder muscle⁴). In all cases in fast neurogenic muscles, there is a correlated development of the sarcoplasmic reticulum involved in calcium transport.

Biosynthesis of bacteriochlorophyll

SIR,—Bacteriochlorophyll (BChl) production in nonsulphur purple photosynthetic bacteria growing anaerobi-

cally is inversely related to light intensity, and introduction of O₂ causes a rapid suppression of pigment synthesis. In a recent report¹, Davies *et al.* summarise findings which lead them to conclude "the original suggestion of Cohen-Bazire *et al.*² that the synthesis of BChl is controlled by the redox state of one or more of the components of the electron transport chain, is correct."

In this connection, Davies *et al.* cite experiments³ with intact cells in which various respiratory electron transport inhibitors were found to interfere with the synthesis of magnesium protoporphyrin. Since interruption of electron transport in intact cells can be expected to have numerous ramifying effects, there is reason to question the statement that "one or more of these [electron transport] components has been shown to be directly involved in the insertion of magnesium into protoporphyrin".

Davies *et al.*¹ suggest that "direct" control of BChl synthesis by O₂ (and light intensity) is also effected through regulation of aminolaevulinate (ALA) synthetase, the first enzyme of tetrapyrrole biosynthesis. They assert that ALA synthetase may be regulated by a trisulphide of glutathione or cystine which, in its oxidised form, increases activity of the enzyme. According to their scheme, oxygen (or light) has the effect of oxidising carriers of the electron transport chain, which in turn cause oxidation of an unidentified sulphhydryl compound to its disulphide form; the latter than is presumed to oxidise the "reduced polysulphide activator" to its active (stimulatory) state. On this basis, O₂ might be expected to accelerate BChl synthesis, rather than inhibit, but Davies *et al.*¹ seem to suggest that O₂ also disturbs sulphur metabolism so as to interfere with biosynthesis of the trisulphide activator. Elsewhere⁴, Neuberger *et al.* express the view that "oxygenation may lead to direct inactivation of the activator". We have been unable to rationalise the regulation of BChl synthesis by oxygen in terms of their interpretations.

Our recent experiments⁵ with mutants of *Rhodospseudomonas capsulata*, blocked at different points in

respiratory electron transport, demonstrate that the rapid inhibition of BChl synthesis by oxygen is independent of the cell's metabolic capacity to use O₂ as a terminal oxidant or to deliver reducing equivalents to the aerobic electron transport system. This argues cogently against the "redox carrier governor" postulation for regulation of BChl synthesis, and we have proposed an alternative working hypothesis in the study cited⁵.

DR NEUBERGER REPLIES: At the time when the paper by Davies *et al.*¹ was first submitted to *Nature*, all the known facts discovered by others and ourselves were compatible with the proposition first put forward by Cohen-Bazire *et al.* in 1957 that the electron transport chain in some way exerted a direct control over bacterial chlorophyll synthesis. Later experiments by Marrs and Gest published in 1973² and our own work published later in that year³ indicated that the effects of oxygen may be more specific and may be exerted through its action on sulphur metabolism, and in particular may be due to the depletion of the cellular content of a trisulphide activator of the enzyme. In this respect we are in

essential agreement with Gest and Marrs and our current work also is in accord with this general idea. It is, however, still possible that the activation process, which was first described by Marriott *et al.*⁴, involves in some way the electron transport chain. The possibility also exists that similar mechanisms operate *in vivo*, but data at present available do not allow a definite conclusion to be reached.

Microstructure of magnesium oxychloride cements

SIR,—Matkovic and Young in their article on the microstructure of magnesium oxychloride cements¹ reported some interesting observations, and raised some points for discussion. I would like to discuss those points which have wider implications.

The authors coated their samples with a Au-Pd layer of unstated thickness before examination in a scanning electron microscope (SEM). In the case of the metal coated specimen, SEM only reveals the outer topography of the metal layer. Figure 1 shows a section through three parallel needles each 2,000 Å thick, separated by 500 Å. The volume porosity of this packing is 37%. Assuming that the depositing vapour had a uniform density, any layer more than 250 Å (that is $\frac{1}{8}$ of the needle diameter) thick, will start to coalesce them. If the film thickness is 500 Å ($\frac{1}{4}$ of the needle diameter) the shaded areas of Fig. 1 will receive double the amount of metal necessary to fill them up. This excess metal will pile up locally, making the outer surface slightly undulated (indicated by the broken lines), and will be difficult to resolve into three. A thicker coating will make them appear monolithic. With lower porosity, a lower film thickness will be necessary to submerge them. If the needles are diverging, a metal film of proper thickness will make them appear to intergrow at the points of nearest approach, though in reality they do not. It can be seen that unless the coating thickness is adjusted to take care of particle size and density

Fig. 1 A section through three parallel needles, each 2,000 Å thick, separated from one another by 500 Å. The broken lines indicate the slightly undulating outer surface formed by excess metal.

of packing in the specimen, quite a misleading topography may result.

Figure 1c of ref. 1 shows that the average apparent diameter of the crystals is about 1,200 Å. For the real diameter, twice the film thickness has to be deducted from that figure. For crystals of 1,200 Å real diameter, a film thickness of 150 Å or less will be required before it can be distinguished whether they are intergrowing or not. The above crystals were, however, the initial reaction products. The subsequent products are expected to be smaller and more densely packed. It is perhaps not surprising that the authors found that in older samples, the crystals were intergrown and the samples had a monolithic appearance. The smoothness of the cracked surfaces in their Fig. 3 can also be explained on this basis, though there are other alternatives.

The term 'intergrowth' has been used rather uncritically. There are two types of crystal-crystal intergrowth. A crystal may intergrow into another crystal without having any structural continuity, like a nail in a piece of wood. This is a special case of mechanical intergrowth. The second type of intergrowth involves structural continuity between the participating crystals. For this type of intergrowth to occur the crystals need to meet each other in definite orientations, satisfying the laws of twinning. Matkovic and Young seem to imply the second type of intergrowth. I wonder if they have tried, on this basis, an order of magnitude calculation on the probability of formation of a three dimensional load bearing structure. The result of that calculation would be quite illuminating.

Note added in proof: Re-examination of Fig. 1c reveals isolated needles whose real diameters are equal to the stated film thickness. How many more of them were in the real sample?

¹ Matkovic, B., and Young, J. F., *Nature phys. Sci.*, **246**, 79 (1973).

DRS YOUNG AND MATKOVIC REPLY:

It is certainly true that one of the problems of SEM is the need to have a conducting layer on the surface of inorganic materials. We are aware of the inherent problems of metal coatings, but do not think it invalidates the results presented in the original article. We used comparatively light coatings (~250 Å) of gold-palladium, and comparisons of such coatings with pure carbon coatings (which are transparent to secondary electrons) on samples of portland cement compounds, have not shown substantial differences in microstructural details. We therefore have confidence in the qualitative observation described in our article.

The term 'intergrowth' has been deliberately used in a vague sense and we regret any resultant misinterpretations. On the basis of SEM observations alone it is not possible to draw any definite conclusions concerning the exact interactions between crystals. We feel that, in order to explain the high mechanical strengths, these interactions must be stronger than weak Van der Waals surface forces, but may range from strong 'solid-solid contacts' postulated for hydrated portland cements¹, to true structural continuity.

Finally, we emphasise that these results are preliminary observations. We advanced our ideas in the interests of suggesting an alternative approach to the problem of strength development in cementitious systems. We realise that SEM cannot provide all the answers and we feel that, at present, attempts to make quantitative predictions may be premature.

Photosynthesis in leaves exposed to SO₂ and NO₂

SIR,—Bell and Clough¹ have reported that the growth of S23 ryegrass was substantially reduced by exposure to 12 p.p.m. (parts per hundred million) SO₂. Bleasdale² grew the same variety of ryegrass in greenhouses ventilated with polluted air from out-of-doors on a suburban site in Manchester and compared the growth with that in a greenhouse ventilated with purified air. There were reductions in the dry weight of the plants amounting to 57% in the polluted atmosphere, even though the SO₂ concentrations were below 3 p.p.m. for 39 out of 42 d and the daily

means did not rise above 9 p.p.h.m. at any time.

Bleasdale's data appear to show that S23 ryegrass is more sensitive to SO_2 than is apparent from the study by Bell and Clough. This discrepancy may be the result of their having performed experiments in different conditions, but it may equally have resulted from Bell and Clough's simulated SO_2 pollution rather than polluted air from outside. In Bleasdale's experiments other air pollutants would also have been present. One such is NO_2 . This is found in polluted atmospheres because NO is produced by combination when fossil fuels are burnt, and is quickly oxidised in air to NO_2 . We have recently completed some experiments in which the combined effects of SO_2 and NO_2 pollution on photosynthesis in the pea,

p.p.h.m. and above of both SO_2 and NO_2 were found to produce visible lesions on intact plants. Visible injury to crop plants after simultaneous exposure to SO_2 and NO_2 has been reported previously³.

Our data suggest that combined effects of SO_2 and NO_2 might explain the growth inhibition caused by urban pollution², and that this possibility should be considered in future studies.

Fig. 1 Effects of simulated SO_2 and NO_2 pollution on net photosynthesis in *Pisum sativum*. Fumigation conditions: 1.20 air changes min^{-1} ; temperature, 21°C ; light intensity, $73\text{ J}^{-2}\text{ s}^{-1}$; water vapour pressure deficit, 995 N m^{-2} .

Pisum sativum, were examined over a concentration range of 0-25 p.p.h.m. for each gas. Initially, exposure to these pollutants increased net photosynthesis, but the effect was short lived and a substantial inhibition soon followed. The magnitude of this inhibition for 15 different treatments is shown in Fig. 1, with the control included for comparison. Analysis of this factorial experiment revealed statistically significant effects of SO_2 and NO_2 ($P < 0.001$ in both cases) but no significant $\text{SO}_2 \times \text{NO}_2$ interaction. It is clear, however, that the effects of the two pollutants are at least additive. These observations were made on detached leaves and no visible injury accompanied the depression of net photosynthesis, but more prolonged exposures to concentrations of 10

Regulation of albumin-bound tryptophan

SIR—Madras *et al.*¹ recently reported on the effect of tryptophan concentrations in serum and brain concerning its conversion to serotonin in rats. This and related work have been summarised by Fernstrom and Wurtman² who suggest that albumin-bound tryptophan is the precursor of serotonin. These authors^{1,2} have found that decreased nonesterified fatty acid content (albumin-bound) in the serum caused by administration of carbohydrate or insulin results in higher concentrations of albumin-bound tryptophan, while fasting (high fatty acid content in serum) results in lower albumin-bound tryptophan levels, suggesting that fatty acids competitively prevent the binding of tryptophan by albumin.

If one assumes a serum albumin concentration of 4 g per 100 ml, the data of Madras *et al.*¹, on the concentrations of serum-bound tryptophan and fatty acids can be converted into moles of tryptophan or fatty acid bound moles of serum albumin (Table 1). Thus conditions which decrease concentrations of fatty acids in the serum increase concentrations of albumin-bound tryptophan. McMenamy and Oncley³ found that bovine albumin bound 1 mol of L-tryptophan per mol of albumin. Addition of fatty acid decreased the binding capacity of the albumin for tryptophan by 0.1 mol for each mol of fatty acid. When 2.0 mol of oleate was present the albumin bound 0.75 mol of tryptophan.

Since 2.0 mol of fatty acid per mol of albumin represents the largest fatty acid ratio in Table 1, I assume that a minimum of 0.75 mol of tryptophan could be bound to the albumin rather than the maximum of 0.135 mol observed if fatty acid competition were the limiting factor.

The free energy (-7.2), enthalpy (-14.5) and entropy (-24) changes determined by Fairclough and Fruton⁴ for the binding of L-tryptophan to serum albumin are similar to those observed for binding of iodide⁵, lysolecithin⁶ and probably dodecyl sulphate⁵ to the high energy site of albumin. Thus such a material, which is strongly bound to the albumin, might decrease the amount of this site available for tryptophan and so function, along with fatty acids, to regulate the amount of tryptophan bound.

book reviews

De Broglie's philosophy

Louis de Broglie: Sa conception du monde physique, By A. George, et al. Pp. xxviii + 387. (Gauthier — Villars: Paris, 1973.)

LOUIS DE BROGLIE'S 80th birthday (August 15, 1972) came close enough to the 50th anniversary of his three famous notes to *Comptes Rendus* (September–October 1923) and the publication of his doctoral thesis (November 25, 1924) to warrant a double celebration. This collection of articles by his close colleagues, old and young, describes both his long career as a teacher and leader of research and the contributions that he and his pupils have made to "the past and the future of wave mechanics". Handsomely produced, elegantly phrased, and well integrated despite more than twenty different authors, it will prove a valuable source for biographers and for historians of science.

The accuracy of the personal picture cannot be easily estimated in a work of this kind, whose whole emphasis is naturally on the positive and virtuous — the guide, philosopher and friend, the lucid and eloquent teacher, the imaginative scientific intellect, still enthusiastic in old age, still able to state, more clearly than his pupils, the essential stages in his own scientific development and his own analysis of current problems. No man is perfect; but we do well to admire these qualities of greatness.

But the scientific work, being in the public domain, must be appraised more judiciously. Its standing depends not on the fact that it was done by M. de Broglie, but that it conforms to reality and is accepted by other competent scientific experts. This is the harsh law of science which defers not to prince, professor or poet.

Of the thesis of 1924 there can only be the highest praise. The very idea of 'matter waves' is the most revolutionary innovation in the philosophy of nature since the ancient Greeks. This significant step in modern physics was no mere stumble into the unknown, but a tremendous leap, gracefully poised on the classical principles of Fermat and Maupertuis but vaulting beyond Einstein's conjecture on the particulate nature of radiation. The first half of this book deals with the theoretical background of this brilliant paper, and on some of its modern

consequences, in electron microscopy, and so on.

So profound, indeed, was the revolution of thought that the revolutionary has spent the rest of his life trying to resist the further, yet more radical, statistical interpretation of the wave function. The papers in the second half of this volume record the considerable efforts of de Broglie and his school to reconcile waves with particles in a more deterministic scheme. Since this work is largely ignored by other theoretical physicists, one must ask why it has not found wide acceptance.

Nobody who has seriously grappled with (let alone had to teach!) the modern paradigm of quantum theory can feel completely satisfied with its present form. The essential localisation of the particle event is not intuitively consistent with the equally certain evidence of interference between extended wave fields. The fantastically precise discreteness of the rest mass and charge of an electron is a fact of nature that is difficult to swallow philosophically. The operator formalism of Heisenberg and Dirac seems to answer all the practical questions but leaves hollow the interior reality. The extraordinary paradox of a physical quantity that seems to depend upon the state of mind of the physicist is not to be shrugged off without comment.

There is, of course, a vast literature on these problems, to which the de Broglie school make almost no reference. Their theme is the ultimate 'reality' (potentially unequivocal observability?) of wave fields, of which the particles are singularities and by which they are guided. In his work of the 1930s, de Broglie concentrated on a theory of photons, which were assigned a very small rest mass to make them localisable. In the 1950s, he developed the 'double solution' for the particle singularity and its guiding wave, explaining the statistical phenomena of particle physics as manifestations of a hidden thermodynamic ensemble. Are these models of submicroscopic physics convincing, or worthy of further sustained effort?

Despite many elegant results, the physical systems to which they are applied are very simple (for example a few nearly free electrons) and no new phenomena are predicted for experimental verification. Indeed, it is taken

for granted (although with rather meagre proof) that the whole scheme must be capable of reproducing the results obtained by conventional methods for almost all atomic, nuclear and high energy systems. The de Broglie model is scarcely falsifiable, since it is presented as an alternative 'explanation' of quantum physics at the deepest level, incorporating automatically all existing theoretical achievements such as quantum electrodynamics, many body theory, and broken symmetry schemes.

The necessity for such an explanatory scheme thus rests on metaphysical rather than on physical considerations. The practical physicist may continue to solve all his problems by the conventional operator formalism, and need not learn the more complicated mathematical techniques of non-linear field theory. Until experiment, or some astonishing theoretical coup, demonstrates the practical superiority of the de Broglie interpretation, we can safely ignore it.

Does that explain, or justify, the neglect of this work by almost all orthodox physicists? It would be more honest to say that despite all the mathematical effort that has been lavished on it, the whole project rests upon too narrow a foundation of hypothesis and technique. The natural phenomena are richer (for example neutrinos, muons, pions, strong and weak forces) and our mathematical resources more diverse (finite and continuous groups, topology, tensor calculus and so on) than this book seems to imagine. For aesthetic reasons, and in modest deference to the unknown knowledge of future men, we do well to doubt that physics is conceivable only in the manner inherited from Newton, Laplace and Einstein. I would rather live uncomfortably with the paradoxes of quantum physics, hoping that some day they will be resolved, than accept, for the sake of peace of mind, a well meant but essentially backward looking scheme which promises more than it has yet achieved.

JOHN ZIMAN

Fine structure of algae

The Fine Structure of Algal Cells. By John D. Dodge. Pp. xii + 261. (Academic: London and New York, 1973.) £6.

THIS book is well produced and many of the illustrations will doubtless be

turned into lantern slides. The text, on the other hand, reads like a catalogue, with all the disadvantages of this type of format. Moreover there is no flicker of interpretative insight directed towards a reader who may not spontaneously appreciate the scientific interest of the phenomena or structures described.

This is not all the result of compression to reduce costs since, minor errors or omissions apart, some hazards to potential users have been deliberately inserted by the author or publisher without effecting great savings. Thus all too many micrographs are labelled with a generic name only, as if species of algae do not matter. One picture of scales is even labelled "*Chrysochromulina?*". Perhaps some tyro may value this and memorise it as an examination gimmick. An older reader, on the other hand, perhaps a non-botanist hoping to enter the fine structure field personally, must learn at the outset that, especially among algae, species may matter very much and carelessness here can invalidate or render unrepeatable the most elaborate exercises of other kinds. Any book which suggests, even by its format, that this is not so is being less than helpful to a serious and desirable type of reader.

Further, the omission of titles from the papers listed at the end, removes at a stroke the future usefulness of the book as a work of reference while greatly increasing the difficulty of effective proof reading. Thus on page 166 an important topic is said to have recently been summarised by an author dated 1972e while in the literature list one finds only 1972f (subject unknown) following 1972d (subject also unknown).

While, therefore, this book will be useful for a limited time and purpose for which it ought to be bought by libraries, it is not one which I would give as a present to a friend, colleague or student. Considering the intrinsic interest and beauty of the subject this is disappointing.

I. MANTON

The first clover leaves

The Primary Structure of Transfer RNA. By T. V. Venkster. Translated from Russian by Basil Haigh. Pp. x+296. (Plenum: New York and London, 1973.) \$29.

THIS monograph sets out to cover the entire field of transfer RNA primary structure in textbook form. It is an extended edition of a Russian text first published in 1968 and in this revised version surveys the literature up to July 1971. Each of the 22 transfer RNAs which had been sequenced by that time are described in considerable detail. The constant features of transfer

RNA architecture are also discussed, together with the evidence supporting the clover leaf hypothesis of the base-pairing of transfer RNA sequences. Little serious attempt is, however, made to relate features of individual sequences to the functional centres which determine the acceptor or adaptor roles of transfer RNA, other than in a consideration of the codon recognition properties of different anticodon loop structures. Hence those wishing to comprehend the structure-function relationship of transfer RNA will not find in this monograph a topical account of how the nucleotide sequence of a transfer RNA molecule can determine its function. The three-dimensional structure of transfer RNA obtained from X-ray crystallography is now clearly on the horizon and it should soon be possible to provide a more meaningful topological interpretation of the significance of those regions of transfer RNA sequences which lie outside the anticodon.

Much of this book is given over to a clear and detailed account of how the first few transfer RNA sequences were determined. The author takes us back to the initial attempts to determine nucleic acid primary structures and enables us to re-live that exciting period when the first few transfer RNAs were being sequenced. A considerable proportion of the narrative describes methods for the sequencing of non-radioactive RNA and many of these procedures have been largely supplanted by newer methods of sequence analysis which greatly reduce the work load of the experimentalist. There is little more than passing reference to the methods developed in Sanger's laboratory for sequencing ³²P-labelled RNA, even though most transfer RNA sequences are now derived using these techniques. Furthermore several other publications give a much more comprehensive and useful description of nucleic acid sequencing.

The chapter of this book which discusses the minor nucleotides of transfer RNA is by far the most topical and presents a thorough account of the physicochemical properties of these components. In view of the elaborate system of enzymes which exists for modifying transfer RNA it is hard to conceive that the modifications do not have an important biological function. Nevertheless the more inquisitive reader would probably wish to see expanded the sections of this book which describe the roles of the different isoacceptor transfer RNAs and the functions of the different minor components of transfer RNA.

As a result of the considerable effort now being expended in determining nucleic acid structures it is clearly

almost impossible for any book on transfer RNA to be up to date by the time that it is published. It has taken three years for the English version of this book to appear and during that time the number of sequenced transfer RNAs has increased from 22 to nearly 70. A complete summary of all known transfer RNA structures (*The Handbook of Nucleic Acid Sequences*, by B. G. Barrell and B. F. C. Clark) has recently been published as a loose-leaved folder by Joynson-Bruvver, Oxford. This is to be annually updated and will be rather more realistically priced. T. V. Venkster's book is more of value as a comprehensive account of the beginnings of nucleic acid sequencing.

P. W. PIPER

Evolution of plants

Chromosome Botany and the Origins of Cultivated Plants. By C. D. Darlington. Third (revised) edition. Pp. xvii+237. (Allen and Unwin: London, September 1973.) £4.40.

THE fascination of plant evolution is the great variety of mechanisms that have been involved. Plant species have certainly not plodded dully through time, losing a few genes here, gaining a few genes there: they have flashed into polyploidy, chromosome structural changes, inbreeding, apomixis, hybridity, with almost breathtaking frequency. The plant species which have stuck to an ordinary outbreeding diploid type of evolution are probably fewer than those which have not.

Since so much of this cunning and opportunism is tied up with chromosomal change, a book on chromosomes in plant evolution, by the cytologist to whom much of our understanding of chromosomes is due, is surely to be welcomed and respected, especially since it now reaches the eminence of a third edition. The book is also important because it is one of the very few in which the origins of cultivated plants are discussed, making use of recent evidence.

Alas for high hopes. The trouble is that the author falls a victim of his own enthusiasm. One is given too great an impression that plant evolution can be explained solely in terms of chromosomes: changes at the level of the gene cannot be disregarded. One is given a fascinating picture, but one which is capricious and worrying, and sometimes difficult to understand.

Yet the book contains the distillation of a lifetime: a provocative variety of evidence and conclusions on plant evolution that is unique, and a collection of information on crop plant evolution that is not available elsewhere. This is the reward for the reader.

A. D. BRADSHAW

Sad time for salmon

International Atlantic Salmon Symposium. Edited by Morden W. Smith and Wilfred M. Carter. Pp. xi+504. (Atlantic Salmon Research Trust: Fanham, Surrey; International Atlantic Salmon Foundation; New Brunswick, 1973.) £6.50 boards; £5 paper.

THIS collection of papers is the published proceedings of the "Symposium on the Atlantic Salmon: the Management, Biology and Survival of the Species", held at the Huntsman Marine Laboratory, St Andrews, New Brunswick, in September 1972. It consists of thirty-one major contributions under six main headings; the effects of man and the changing environment, physiology, ecology, aquaculture, environmental engineering and fishery economics, and conservation and fisheries.

With such a wide-ranging approach to the problems which surround the Atlantic salmon it is not surprising that several of the papers seem to have little direct relevance to the main objects of the symposium. One contribution invokes the aid of systems analysis for salmon conservation in a dauntingly titled paper, "the FASTRR concept (Facility for Atlantic Salmon Technological Research and Restoration). A status report". This concludes "the design and construction of an improved intensive culture hatchery depends on the determination of biological and physical needs, their estimated implementation and operating costs as balanced against predicted benefit to the overall project objectives. Elements of this study hopefully will ease the decision maker's task of quantitative initial assessment, choosing between alternates, and managing efficiently...". (One wonders what Frank Buckland, Inspector of Salmon Fisheries, 1867-1879, who managed to hatch salmon and trout eggs in the kitchen of his home in Albany Street, London, would have said of that?)

The salmon, in a unique way, is the focus of emotional attitudes. As an economic, leisure, or food resource it is probably without equal, but its decline in the industrialised and heavily populated North Atlantic countries has been quite dramatic. Reaction to dwindling salmon stocks in many countries suggests that although this may be more or less acceptable, it is clearly not acceptable for other nations to exploit the stocks outwith the national boundaries. Thus, the relatively recently developed high-seas fisheries conducted off the coast of West Greenland, and also in the Norwegian Sea, has resulted in a crisis within the salmon-producing countries, made still more emotional by the fact

that the country mainly operating the fishery is not a salmon producer. This development has placed the conservation of the Atlantic salmon firmly in the field of international relations, and as Dr Wilfrid M. Carter, co-editor of this volume, remarks, "the Atlantic salmon, perhaps more than any other fish has become symptomatic of the unwillingness of the international community to face and to solve critical problems...".

The contributions in this volume essentially fall into three categories (although they are not so divided by the organisers): the biological papers, some of which have direct relevance to the conservation of the species, papers on the management of stocks, and those directly related to the international management of the species. This last category would seem to have the most direct bearing on the major problem confronting the salmon. In this context, the review by B. B. Parrish of the work on the ICES/ICNAF Joint Working Party on the North Atlantic Salmon is a major contribution, summarising the problems involved and distinguishing the areas of biological knowledge that require to be clarified before more precise assessments of their effects can be made. But as D. L. McKernan points out elsewhere in the volume, the adoption of an ICNAF formula to phase out the non-native high seas fishery off Greenland, and to impose a catch limit on the inshore fishery, offers reason to be cautiously optimistic for the future of the Atlantic salmon.

ALWYNE WHEELER

Weather forecast

Radar Observation of the Atmosphere. By L. J. Battan. Pp. x+324. (University of Chicago: Chicago and London, 1973.) £7.15.

THERE has been a considerable increase during the past two decades in the use of electronic techniques for the remote sensing of the atmosphere, with radar playing an important if not dominant part. So much new material had become available that the author has carried out an extensive revision of his earlier work *Radar Meteorology*, first published in 1959. The present volume under its new title is solely concerned with the application of microwave radar in the study of atmospheric phenomena including precipitation, cloud, wind and clear air turbulence. The author has succeeded in covering most of the relevant material in less than 300 pages of text. This should have considerable appeal to a wide scientific readership apart from meteorologists, particularly those who lack a specific background in electronics.

The principles of radar are well illustrated although the author's very brief introduction concerning the properties of electromagnetic waves will hardly benefit a reader who is not already familiar with the subject. The remainder of the book deals with radar applications and the related atmospheric physics in appreciable depth. Although space may have been limited it would have been attractive if the author had covered in the same manner some aspects of upper atmospheric work including chaff and meteor radar as well as incoherent scatter techniques. Numerous technical details of radar installations are given in an appendix and readers will welcome a very comprehensive and up to date list of references. H. G. MULLER

Strange coincidence

The Challenge of Chance: Experiments and Speculations. By Alister Hardy, Robert Harvie and Arthur Koestler. Pp. 280. (Hutchinson: London, November 1973.) £3.

DURING a recent visit to America I was met at Roanoke Airport by my friend the statistician, I. J. Good, of the Virginia Polytechnic. Good excitedly asked me what type of plane I had flown in on and when I told him a Boeing 727 he cried "I knew it. I knew it". He then pointed to the licence plate of his Ford Mustang, which boldly featured the inscription "CRE 727". Permanent testimony to the happy correspondence between my initials, the plane I had flown in and Jack Good's car exists in the form of a licence plate which now adorns my office wall.

If you like stories of this kind you will revel in *Challenge of Chance*, which is described on the blurb as being "the first book to be written jointly by a Fellow of the Royal Society and a Fellow of the Royal Society of Literature—with a psychologist providing the bridge between the two cultures". The interdisciplinary flavour of the work is certainly striking, but the bridge is rather a shaky one. The book falls uneasily into three separate chunks—the first an account by Sir Alister of an "unsuccessful" mass extra-sensory perception experiment, the second a thirty page discussion by Harvie of probability theory and how puzzling it all is; the third a long essay by Koestler on some of the strange things that have happened to him, his friends and his correspondents. The majority of the strange things, I hasten to add, are somewhat more marvellous than the CRE 727 example. Hardy's experiment incidentally—a group ESP test in the Caxton Hall—was only unsuccessful in that no evidence of

telepathy was demonstrated. A subsequent and more elaborate search through the data revealed peculiar similarities in the guessing patterns of people seated near to each other in the group test. There are of course a number of possible explanations for such a finding, but Sir Alister considers it to be an example of "the coincidental coming together in time of similar ideas". But what, he asks, do we mean by coincidence anyway? This leads with a bump into the statistician's contribution, where again the inner meaning of the word coincidence is explored. Here the argument appears to be that if you riffle about long enough with sets of numbers you'll discover peculiar sequences in them—but sooner than you ought to have done by chance. Somewhere about here one crosses the transitional zone between statistics and pyramidology and I must confess to not being absolutely clear on occasions on which side of the zone Mr Harvie lies.

One is left in no doubt where Mr Koestler stands however. He doesn't actually use the word 'pyramidology' but like the pyramidologists he clearly believes that man should be very alert to the hidden meanings buried in the depths of what appear to be fairly straightforward objects or events. His section of the book is a compendium of the bizarre and the unlikely—psychic visions, poltergeist-like raps, unusual dreams, chance meetings in strange places and, of course, correspondences of the mystic car number variety. From here he argues that the sheer weight of human testimony to the vast array of oddities of this kind forces one to dispose of the word 'chance' in an explanatory role. Chance itself is a meaningless word which tells us nothing whatsoever about the universe and merely allows us to duck the issue of why such things happen so that we can preserve the creaky yet primary principle of causality. In his final section, ponderously titled "Speculations on Problems Beyond our Present Understanding", he returns to the theme of his previous work, "Roots of Coincidence", arguing that the peculiar phenomena of parapsychology are no longer peculiar in the light of recent discoveries in quantum physics. "Enlightened physicists" he tells us patronisingly, are now willing to concede this. The book is a frank statement of personal opinion and Koestler's segment in particular is highly readable. There's also not much doubt that it will be sweet music to the ears of thousands of readers, including a fair number of scientists who refish the anti-materialistic backlash which Koestler so heartily champions. Curiously, I think it is the parapsychologists, or at least those who have spent

their lives attempting to trap the alleged and elusive phenomena of ESP by using the methods of experimental psychology, who will find the book most disquieting. For if there is a central argument which emerges it is that there are facets of the Universe—large facets of it—which will resist and even reject study by the traditional methods of science. This, the book implies, is the principal reason for parapsychologists' signal lack of progress in attempting to 'prove' the existence of ESP. A discouraging argument I would have felt, and if anyone cared to apply it to other areas of science, the consequences for research could be pretty peculiar. Most scientists therefore will find this a glum rather than a heartening book. Perhaps 'glumly entertaining' would be the best way to describe it.

CHRISTOPHER EVANS

Thrips

Thrips: Their Biology, Ecology and Economic Importance. By Trevor Lewis. Pp. xv+349. (Academic: London and New York, November 1973.) £7.80: \$22.

THE Thysanoptera are a very interesting and important group of insects which are often ignored, apart from a few economically important species, such as the cereal thrips (*Limothrips cerealium*) or the onion thrips (*Thrips tabaci*). The literature on this group is therefore very scattered, and this book fulfills a long-standing need by bringing together a large part of this information into one place. It is not a book to be read from cover to cover, it is far too concentrated for that, but small doses from parts of it make fascinating reading for the general entomologist. It is a book that would form a valuable addition to the bookshelf of any entomology or ecology laboratory.

It tries to cover a very wide field indeed, often with rather scant information, as this is all that exists. It includes sections on the general biology of the group, rearing and sampling techniques, ecology and economic importance. This wide coverage, while revealing the enormous gaps in our knowledge, does mean that the available information from both the pure ecological literature and the applied literature is brought together, and this in itself makes the book worth having.

On the whole the book is well presented and the numerous appendices are particularly useful. There is however a number of annoying details. For example, I should have liked to see the plates distributed at relevant places in the text, instead of collected at the end, and why put Fig. 47 (a) on page 135 and Fig. 47 (b) and the legend overleaf on page 136? Comparison

would have been very much easier if they had been on facing pages. Errors and inconsistencies inevitably creep into compendia of this sort, but are very few in the present case, for example the corrected catch of thrips at Silwood Park is given on page 205 as "about 18,900 individuals" whereas over the page in Table 24 it is given as 19,900.

The author on the whole has done a good job and this book deserves to be widely used, and will no doubt retain its usefulness for a long time.

S. McNEILL

Marine mathematics

The Structure of Marine Ecosystems. By John H. Steele. Pp. x+128. (Blackwell Scientific: Oxford and London, 1974.) £2.75.

THIS "short work" (the author's words) consists of what, otherwise, might have appeared as two or three research papers, preceded by a general discussion about problems of investigating marine ecosystems and followed by some speculations about the impact of man's activities. The core of the book is the author's mathematical simulation of the pelagic ecosystem in the northern North Sea, presented as typifying open sea environments in temperate or sub-arctic waters.

As Dr Steele says, models of this kind reveal the lacunae in one's knowledge and so determine the kinds of research needed in the field and laboratory. In particular, the model helps to assess the validity of simplifications and identify the points at which greater detail is required.

The book serves these objectives admirably. In addition, it provides growing points for debate on topics such as the differences between terrestrial and marine ecosystems, or the significance of ecologists' icons such as diversity, stability, efficiency, food webs and food chains. In conclusion, Dr Steele argues that the most critical parts of marine ecosystems, and the points at which man's activities impinge most seriously, are at the levels of pelagic herbivores and benthic micro-organisms. He suggests that an increasing effort should be devoted to studies of structure and dynamics at these "lower levels" of the system.

The book is amply illustrated with results of Dr Steele's own research; there is an unexpected and probably unnecessary glossary, a short but valuable list of references and a totally inadequate index. It would be a valuable addition to the personal and institutional libraries of ecologists of all kinds, those who read equations as well as those who do not.

R. S. GLOVER

Stratigraphy

The Boreal Lower Cretaceous. Edited by R. Casey and P. F. Rawson. Pp. 448. (Proceedings of a symposium organised by Queen Mary College, London, and the Institute of Geological Sciences, September 1972; *Geological Journal* Special issues no. 5) (Seel House: Liverpool, 1973.) £9.75.

THIS book has been published with the commendable speed and in the attractive form that one has come to expect from the Seel House Press. Owing to its rather specialised nature it will, however, appeal to a more limited audience than the previous geological volumes in this series. The work is basically a well organised and presented compilation of stratigraphic and palaeontological data for a substantial sector of the northern hemisphere by thirty-two authors, mostly English but with a good representation of leading authorities from North America, France, Germany, Denmark, Poland and the Soviet Union. All the articles are in English, with brief summaries in French and German.

It would be both pointless and beyond the scope of a brief review to comment much on individual articles, which range from syntheses of reconnaissance work in large, relatively unexplored territories to reassessments of classic European localities, but I should perhaps single out Casey's substantial contribution on Jurassic-Cretaceous boundary beds in Europe as being especially welcome, because at last he has been persuaded to publish fully, with good illustrations of ammonites, the data on which are based his interesting conclusions on regional correlation. His views on the position of the Jurassic-Cretaceous boundary are well argued, but he has not managed to convince what one might term the Russian school of workers. A consensus on the subject seems as far away as ever. The overall tone of the articles is one of caution and sobriety, so that one greets with raised eyebrows the bold palaeogeographic reconstructions of H. G. Owen, based on the concept of an Earth expanding rapidly at least from the early Mesozoic to the present day. To paraphrase the molecular biologists, he has thereby offended against the 'central dogma' of current earth science, namely plate tectonics. For those with neither the time nor the inclination to plough through the detail, the editors provide a lucid summary of the proceedings in the concluding article.

The outstanding scientific problem concerning the boreal Lower Cretaceous is the cause of the differentiation of the ammonite, belemnite and to a lesser extent other invertebrate faunas from those of the more extensive

Tethyan Realm. It is welcome to have many pertinent distributional data brought together in one volume, but disappointing that very few authors have properly got to grips with the problem. All too many seem content to present conventional stratigraphic descriptions and discuss matters of correlation, all very necessary as a framework for environmental interpretation but decidedly unstimulating. Those who do try to account for faunal provinces have little new to offer. Most favour some sort of temperature control, while varying salinity and palaeogeographic configurations are proposed as subordinate factors. What I missed is an awareness of the great strides recently made in ecological understanding, with the introduction of new concepts such as environmental stability which may be highly relevant to the matter in question. Furthermore, nobody has made much progress in gathering quantitative data for particular fossil groups on density, diversity and distributional changes in relation to sedimentary facies, palaeolatitude and so on to test particular hypotheses. I sensed that many of the workers in the field are quite satisfied if they can describe and correlate their strata more accurately than before, and that they regard penetrating enquiries into cause and meaning as somewhat beyond their scope. Where problems of environmental interpretation are dealt with it is often in a somewhat token manner, as though they were of secondary importance. I hope that they are deterred by modesty rather than complacency or unimaginativeness. Perhaps the term used to describe their discipline is unduly inhibiting. In the wake of the dramatic advances being made in other branches of earth science there could be today rather less stratigraphy and more stratology.

A. HALLAM

Thin layer chromatography

Inorganic Chromatographic Analysis. By Jan Michal. Translation Editor: Julian F. Tyson. Pp. x+217. (Van Nostrand Reinhold Series in Analytical Chemistry.) (Van Nostrand: London and New York, March 1974.) £9.

THE original Czechoslovak edition of this book appeared in 1970 and the present English translation is therefore some four or five years out of date. With the dramatic advances in high performance column chromatography which have occurred since 1969 a book dealing almost exclusively with paper and thin-layer techniques (PC and TLC), and making no mention of high performance liquid chromatography or gas chromatography is now rather dated. This would not necessarily be

too serious if the author had given an authoritative account of the principles and current equipment, and if he had followed this by a critical appraisal of the application of the techniques in inorganic chemistry. But the treatment of principles is far from adequate: the newcomer would gain little or no insight into the key mechanisms of retention and dispersion of spots or bands in chromatography. He would have to look elsewhere to obtain up-to-date information on equipment; and he would have great difficulty in assimilating the mass of analytical information presented uncritically in the form of a long series of recipes for particular separations, and analyses.

This book cannot be recommended with any enthusiasm, but it may prove useful as a starting point for anyone who wishes to review PC and TLC methods before about 1968, say as a preliminary to devising high performance column methods for some specific separation; but even here its value is prejudiced by the poor subject index and the entire absence of an author index.

J. H. KNOX

Latin American physics

Reaction Dynamics. By F. S. Levin and H. Feshbach. Pp. viii+216. (Documents on Modern Physics.) (Gordon and Breach. New York, London and Paris, July 1973.) £6.65 cloth; £3.50 paper.

I WAS rather disappointed on opening this book to find that it is based on notes taken in some of the lectures of the Latin American School of Physics in 1968. Is it really worthwhile publishing a book in a field of research as rapidly changing as nuclear physics some five years after the event? After reading it I am still not completely convinced.

Levin, whose contribution takes up over three quarters of the book, has helped somewhat by giving a list of supplementary references up to 1972. He makes a survey of many of the "recent" developments in direct nuclear reaction theory, mainly in the description of low energy single particle transfer reactions, such as deuteron stripping. It reads rather like a good review article, with its thorough comparison of theoretical predictions with experiment in over a hundred figures. Most of these predictions were obtained using the distorted wave Born approximation (DWBA), which is the standard way of analysing experimental data, and some space is given to a discussion of the reliability of this as a tool for the extraction of spectroscopic factors. There are ample results on polarisation calculations and the extension of the

DWBA to coupled channel problems. As an alternative theoretical framework, Levin ends with a description of the much more controversial stripping theory of Butler and co-workers, comparing it with both the DWBA and experiment.

The article of Feshbach is very different in character. In just 45 pages it describes some of the features of the theory of nuclear reactions which the author and his collaborators at MIT have developed over the years. Central to this is the interplay between the prompt reactions (the direct reactions discussed by Levin) and the time-delayed ones involving the formation of compound nuclei. By the elimination of the time-delayed components, he shows how an optical model description of the prompt reactions can be formulated, stressing the importance of energy averaging in the scheme. This division into prompt and delayed reactions is of course oversimplistic and Feshbach finishes by considering reactions associated with characteristic times intermediate between these two extremes, such as doorway states. Unlike the Levin work, these feel much more like lecture notes, intended to give the student a broad overall impression of the field. COLIN WILKIN

Light on molecules

Organic Molecular Photophysics. Vol. 1. Edited by John B. Birks. Pp. xvii+600 (Wiley Monographs in Chemical Physics.) (Wiley-Interscience: London and New York, July 1973.) £13.50.

THIS book is the first of two volumes aiming to provide "comprehensive coverage of the field of organic molecular photophysics" and is intended to be complementary to *Photophysics of Aromatic Molecules* written by Birks. This volume contains ten articles, ranging in subject content from organic dye lasers to exciton interactions in organic solids, which have been written, on the whole, by unquestionable experts in their fields.

The quality of individual articles is extremely high. For example, the treatment of radiationless transitions by Henry and Siebrand presents one of the clearest discussions on this complicated topic. The fluorescence characteristics of aromatic molecules is dealt with thoroughly in two chapters, one by Stockburger, considering low pressure environments and the other, by Offen, dealing with fluorescence and absorption effects at high pressures. Triplet-triplet absorptions are discussed from an experimental standpoint by Labhart and Heinzelmann who compile much of the data available up to 1971. There is perhaps some overlap in tabular content between this chapter and "Photo-

physics of Aromatic Molecules". Dye lasers are dealt with from an experimental and occasional mathematical approach by Snavely; it is a pity that there is little mention in this article on their obvious uses in, for example, high resolution spectroscopy or fluorescence studies of vibronic states. Klopffner deals thoroughly with intermolecular exciplexes. The first chapter on the spectroscopy of pi-electronic states (by Birks) is introductory in nature and those familiar with the author's first work in this series will find the chapter less useful than the rest of the book. Other articles are written on diffusion-controlled rate processes (Alwattar, Lumb and Birks), electron photoejection from aromatic molecules in condensed media (Lesclaux and Jousset-Dubien) and exciton interactions in organic solids (Svenberg and Gaecintov).

I found it difficult to regard the collection of articles as "integrated" since the book reads more like a high quality "Advances in . . ." series. It could be argued that most of the review articles are available elsewhere although not in a single volume. I hope that the high standard of individual articles is maintained in volume 2. This volume would be a very useful addition to the library of individual researchers engaged in photochemistry and photophysics although it would not be essential. M. A. WEST

Atmospheric chemistry

Chemistry of the Lower Atmosphere. Edited by S. I. Rasool. Pp. xii+335. (Plenum: New York and London, 1973.) \$26.

THE book is a collection of six chapters on various aspects of atmospheric physics and chemistry by six different authors. Like all such collections it is variable in emphasis, standard and depth of treatment of subject. Because of this it is difficult to decide to what audience the book is aimed.

Dealing with each chapter in turn, the first of about 60 pages entitled "Role of Natural and Anthropogenic Pollutants in Cloud and Precipitation Formation", by Professor H. R. Pruppacher of UCLA, does no more than summarise what can be found in the standard texts on cloud microphysics. Although lip service is paid to the importance of cloud dynamics, that is the air motions leading to cloud condensation, and the interaction between cloud microphysics and dynamics, in fact the chapter is almost exclusively devoted to the microphysics of clouds. There is nothing on the possible modification of precipitation due to anthropogenic pollutants except a brief uncritical reference to some evidence that

urban areas experience more precipitation than their adjoining rural environment.

The next chapter, of about 40 pages on "Particulate Matter in the Lower Atmosphere" by Dr R. D. Cadle of NCAR, is a standard review of the main physical and chemical properties of the tropospheric and stratospheric aerosols. The sections on aspects of the atmospheric sulphur cycle and the scavenging processes for particulates in the troposphere duplicate more extensive treatments of these aspects in later chapters.

The third chapter is on "Removal Processes of Gaseous and Particulate Pollutants" by Dr G. M. Hidy, and is perhaps the best chapter in the book. It contains a scholarly and comprehensive treatment of the atmospheric scavenging processes.

"The Global Sulphur Cycle" is the title of the next section (24 pages) by Dr J. P. Friend. It summarises effectively the current state of knowledge of sources, sinks and reservoirs of sulphur. It is nice to see an author emphasising the limitations of his treatment.

The next contribution of 46 pages is perhaps the one closest to the central theme of the book, in that it deals with "The Chemical basis for Climate Change". The authors are Drs Schneider and Kellogg of NCAR. In it are described the qualitative arguments used to ascribe possible causal relationships between changes in atmospheric composition and climate. It also gives the reader some feel for the vast problems involved in any worthwhile quantitative modelling of climatic change.

The last chapter of 79 pages, by Dr C. D. Keeling, is devoted to the carbon dioxide cycle. It could be argued that the mathematical detail contained in this chapter is out of proportion to that in the rest of the book, but nevertheless it gives a very real insight into the various interacting factors concerned with the atmosphere, the oceans and the biosphere which control the concentration of CO₂ in our atmosphere.

In summary, the book has little to offer those workers actively engaged in the fields of atmospheric chemistry and meteorology. But at a time when more and more scientists outside the fields of atmospheric physics and chemistry are taking an interest in pollution matters, this book provides a useful introduction to some aspects of the subject. P. GOLDSMITH

Erratum

The price given for *Comparative Vertebrate Morphology* by Douglas and Molly Webster (reviewed in *Nature*, 249, 866: 1974) was incorrect; it should have been \$14.95 and £7.

science on television

One giant bore

by John Gribbin

ON JULY 20, just five years to the day since Neil Armstrong and Edwin Aldrin stepped on to the Moon, the BBC broadcast, with much huffing and puffing from its publicity machine, "Moonwalk One"; "... a NASA-commissioned documentary which records the moon landing adventure in minute and breathtaking detail", to quote from the *Radio Times*.

Minute the detail may have been, but the programme was hardly breathtaking, except insofar as the encouragement of yawning could be said to constitute a breathtaking spectacle. This was an opportunity missed on the grand scale; a film which should be preserved as a guide to producers in how not to present exciting science on television.

Shots of Saturn rockets taking off are now something of a cliché, but still sufficiently spectacular to justify inclusion in such a supposedly definitive feature. But there was little further material with a comparable visual impact, in spite of the existence of miles of such film in the NASA archives. The reason for this seems to have been a desire on the part of the makers to use only genuine Apollo 11 material, in line with the programme's title.

That would be laudable enough if the material was any good, but it simply is

not. To me, the most dramatic thing about the first Moon landing was that it was covered live on TV around the world. As far as I know, this was just about the only aspect of the mission not predicted by the science fiction writers.

But in retrospect those first pictures were not at all good. Since Apollo 11, we have become even more blasé about the TV coverage of Apollo, and used to pictures which are not just shaky grey blurs labelled "Live from the Moon", but rather in full colour and coming from a camera which is controlled from Earth so that we can watch the astronauts at work.

The answer, surely, would have been to produce a documentary not just about Apollo 11 but about the whole Moon adventure, using material from the later missions which is so ideally suited to the TV medium. As it was, whether through the paucity of good Apollo 11 material or as policy, "Moonwalk One" fell back on long, boring sections of padding. Shots of row upon row of the 'backroom boys' at Houston no doubt brought a warm glow to the hearts of their Moms and kids back home, but told us little of the excitement and importance of the mission. And views of good American citizens flocking lemming like to the beach to watch the launch will no doubt provide useful information for sociologists studying the phenomenon of how dramatically public interest in the Apollo

programme waned after the first mission. But that, surely, was not what the programme was all about.

Even the genuinely exciting parts of the programme—perhaps one sixth of its ninety-minute length—were marred by obtrusive and inappropriate background music in the sub-2001 tradition, and the few graphic aids used were not in the same league as the famous 'simulation' which filled in the gaps when the live Apollo broadcasts were being made. Some heretics, indeed, have been known to argue that the simulation was, visually, the best part of those missions; they have a point, but perhaps those of them who watched "Moonwalk One" were mollified by the segment of old Buck Rogers' film clips. These provided the dramatic highlight of the programme, which declined monotonically in interest for its final hour.

The tone of the whole proceedings is perhaps best summed up by noting that the *Radio Times* even failed to quote Armstrong's famous and carefully rehearsed *ad lib* correctly: "One small step for man, one big step for mankind", they said. None out of ten for effort; whoever wrote that should be encouraged to take a giant leap.

But faith in the American way of life and a genuinely breathtaking spectacle was provided to soothe the heated brow within an hour of the end of "Moonwalk One". "Sergeant Bilko", starring Phil Silvers—now, that was worth staying up late for.

obituary

L. C. Dunn

LESLIE C. DUNN, one of America's oldest and most influential geneticists, died unexpectedly on March 19, 1974 still active in a scientific career which spanned more than sixty years, encompassing almost all of the development of modern genetics. His early work established some of the first cases of linkage in mammals, and he was the first to demonstrate similar degrees of linkage between what seemed to be the same kinds of mutations in two distinct species, mice and rats. This

led him to recognise that Mendelian analysis could yield clues to genetic homologies and relationships among species, and thus be applicable to understanding the evolution of natural populations, and formed the basis of his life-long interest in what was to become population genetics. His chief work, however, continued to be genetic analysis, and the major efforts of his laboratory centred on the analysis, by both genetical and embryological methods, of mutations expressed in early stages of embryonic life. The greatest part of this work concerned one extensive series of mutations at a

complex region (T) in the mouse, where he and his colleagues analysed a number of mutations which identified genetic factors essential to early embryonic development. After the elements of this system had been identified in laboratory mice, his interest in natural populations led him to examine feral groups of *Mus* for the presence of these mutations. Most of such populations in North America and Europe proved to be polymorphic for variant genes, usually embryonic lethals or semilethals, belonging to the T series. In searching for explanations of how lethal genes could be main-

tained at high frequencies in natural populations, he found that all alleles at this locus found in the wild were transmitted by heterozygous males to 90–99% of their offspring. This evolutionary force—genetic selection—was thus more powerful than the force of natural selection which would eliminate homozygous embryos.

In addition to these purely scientific activities, Professor Dunn was convinced that relations between nations and cultures could be improved by using scientific collaboration as a bridge. As an army officer returning from Europe in 1919, he helped to provide agencies in the Soviet Union with scientific and technical literature useful in the new state which arose from the revolution of October, 1917. He visited the Soviet Union in 1927 at the time of the 10th Anniversary of the Revolution and thereafter remained in close contact with the active school of genetics there. During the Second World War he was President of the American–Soviet Science Society which undertook the exchange of scientific and technical publications. The same interest in international scientific collaboration was responsible for his part in organising facilities in the USA for enabling scholars displaced by the Nazi takeover of 1933 to continue their work in American universities.

What began then as the Emergency Committee for German Scholars became, as fascism spread, The Emergency Committee in Aid of Displaced

Scholars, and he served as a member of its Executive Committee from 1933 until its dissolution in 1947.

Always interested in questions of race, he began in 1933 actively to apply biological ideas to social and political questions, and to speak and write about heredity in relation to racial prejudice in ways designed for the general public. This led, in collaboration with his friend and colleague, Th. Dobzhansky, to the publication in 1946 of *Heredity, Race and Society*, a book which has now appeared in almost all languages, and subsequently in 1951 to a Unesco Report, *Race and Biology*; both of these were fundamental in establishing the then novel view of human races as populations differing in the relative frequencies of genes shared by most populations.

These activities were an expression not only of his interest in science as an instrument of international education, but of his view that, to be effective, efforts of this sort had eventually to achieve a political forum. Other expressions of the latter view can be found in advisory and consultative work beginning in 1940 in aid of efforts to devise a means for the support of science by the United States Government. He was involved in early drafts of legislation which are predecessors of that which finally brought about the creation of the United States National Science Foundation in 1950.

Professor Dunn received the ScD from Harvard University in 1920, and

after a time at the Agricultural Experiment Station in Storrs, Connecticut, joined the Faculty of Columbia University as Professor of Zoology in 1928. At the time of his death he was Emeritus Professor and Senior Research Scientist at Columbia. He was a member of the National Academy of Sciences (USA), the American Academy of Arts and Sciences, the American Philosophical Society, the Norwegian Academy of Arts and Sciences, and the Academia Patavina; he had been President of the Genetics Society of America, the American Society of Naturalists, and the American Society of Human Genetics. He also served on many editorial boards, and was for some years managing editor of *Genetics*, and later of the *American Naturalist*, the oldest biological journal in the United States. In addition to *Heredity, Race and Society*, his books include *Principles of Genetics*, *Heredity and Evolution in Human Populations*, and *A Short History of Genetics*.

His associates in all his various endeavours will remember him for his stubborn integrity, his sure and immediate grasp of the essentials of any problem or situation, and his complete freedom from pretence or self-importance of any kind. Many of us who knew him will continue to measure our own success by the degree to which we live up to the standards which he set.

APPOINTMENTS VACANT
**UNIVERSITY OF ALBERTA
DEPARTMENT OF ENTOMOLOGY**

Applications are invited for the position of ASSISTANT PROFESSOR, effective April 1, 1975. Qualifications are Ph.D. with postdoctoral experience in insect physiology and interest in aspects of this field applicable to agricultural or forest entomology. Duties include teaching courses in general or applied entomology and insect physiology, the development and direction of a research program and supervision of graduate students in insect physiology and in application of some aspect of physiology to agricultural or forest entomology. Maximum starting salary \$14,043.

Please send full curriculum vitae and names of 3 referees by October 31, 1974 to: Dr George E. Ball, Chairman, Department of Entomology, 260 Agriculture Building, University of Alberta, Edmonton, Alberta T6G 2E3. (297)

**NATIONAL VEGETABLE RESEARCH
STATION**
PLANT PATHOLOGIST

There is a vacancy for an officer to assist with research on vegetable virus diseases. Appointment will be as a Scientific Officer (£1,702-£2,675) or Higher Scientific Officer (£2,461 to £3,371), grade and starting salary being determined according to qualifications and experience. Superannuation scheme with allowance to offset personal contributions. The minimum qualification is a degree (or equivalent) in Botany, or horticultural or agricultural science. Candidates for appointment as 'H.S.O.' will normally be expected to have at least five years' postgraduate experience, including experience in plant virus techniques: training in such work will however be given to a less-experienced appointee. Full particulars and application form (to be returned by August 22, 1974) from the Secretary, N.V.R.S., Wellesbourne, Warwick CV35 9EF. (417)

**SIR GEORGE WILLIAMS
UNIVERSITY**

Montreal, Quebec, Canada

**DEPT. OF BIOLOGICAL SCIENCES
THREE FACULTY POSITIONS**

Three faculty positions available, July 1, 1974: 1 Associate Professor (\$15,400 to \$17,000), 2 Assistant Professors (\$12,000 to \$15,000) depending upon experience and qualifications. Research orientated persons qualified to teach in one or more of the following areas will be considered: Embryology, Plant Ecology, Biostatistics, Introductory Biology. Ph.D. required. Send resume and names of 3 references to:

Dr. H. Enesco, Chairman, Dept. of Biological Sciences, Sir George Williams University, Montreal, Que. H3G 1M8. (429)

UNIVERSITY OF OXFORD**DEPARTMENT OF ZOOLOGY**

There is a vacancy for a research assistant to work on some aspects of insect neurophysiology with Dr. P. L. Miller for one year from October 1974. Applicants should have a good Honours Degree in Zoology. Salary in accordance with age and experience. Applications, with names of two referees, to Dr. P. L. Miller, Dept of Zoology, South Parks Road, Oxford. (481)

Animal Studies Diagnostics Research Radio Pharmaceuticals

Our client is a world leader in research based materials for medicine, research and industry. Continuing commercial success has created the need for two additional research and development scientists. Each should be capable of designing, executing and analysing experiments and of leading a small team. Pension; housing assistance. Salary up to £3,500. Please telephone (01-629 1844 at any time) or write - in confidence - for information to Dr. Clive Jones quoting appropriate reference:

Animal Autoradiography

To establish an effective animal testing unit and to take responsibility for individual research projects. Expertise at both microscopic and macroscopic levels is called for together with a proven record of scientific ability in research or research development. The successful candidate, 25 to 35, could come from a number of disciplines but biological-biochemical expertise would be particularly welcome. Ref. U.5593.

Animal Physiology

Leading a small team he would initially strengthen and extend existing facilities and procedures. Candidates, aged between 25 to 35, will ideally have, in addition to a degree in Pharmacology, experience in metabolism and appreciation of surgical techniques or a biochemical background. Ref. U.5594.

Management Selection Limited

17 Stratton Street, London, W1X 6DB.

☐ BIRMINGHAM ☐ GLASGOW ☐ MANCHESTER

(504)

Food Research Biochemist

RHM Research Limited at High Wycombe is the central research and development unit of the Ranks Hovis McDougall Group. A large team of scientists, accommodated in modern and well-equipped laboratories and pilot plants, is working on a wide variety of projects covering the investigation and evaluation of new food sources and the development of new food products and processes.

A vacancy has arisen in the Biochemistry Department for a scientist to work on a wide range of research and development projects in the field of food protein biochemistry and technology, with special emphasis on vegetable proteins. The successful applicant will also be expected to be aware of development in these areas and those peripheral to them.

Applicants should be completing, or have recently completed, a Ph.D. in food vegetable protein technology, food protein processing or fat-protein interactions in food-stuffs. They should possess a degree of creative flair along with the ability to accept commercial and practical constraints. They should also be willing to work as a member of a team and be able to communicate effectively both verbally and in writing.

This position will carry a salary of around £2,300 per annum along with excellent terms and conditions of employment. Please apply, quoting reference JT/SSO, to:

The Personnel Officer,
The Lord Rank Research Centre,
Lincoln Road,
High Wycombe,
Buckinghamshire HP12 3QR.

(505)

Theoretical Biology Group UNIVERSITY OF UTRECHT

Applications are invited for a lectureship in Theoretical biology. Biologists with strong mathematical background, or mathematicians with strong biological background, could apply at the post on post-doctoral level.

The lecturer will participate in the teaching activities of our group. Research is expected primarily on mathematical models of cellular and multi-cellular processes but other areas of theoretical biology are not excluded.

Appointment by September 1974.

Salary according to qualifications, not less than Pf.2,300, per month. Further information can be obtained from Prof. A. Lindenmayer, Theoretical Biology Group, University of Utrecht, Heidelberglaan 2, Transitorium 11, Utrecht, The Netherlands.

(509)

THE EDINBURGH SCHOOL OF AGRICULTURE AGRICULTURAL ENTOMOLOGIST

Applications are invited for a post in the Crop Health Department from candidates with post-graduate experience in Entomology/Nematology.

Salary scale (under review) Grade III £2,233 to £3,895 plus a cost-of-living safeguard and a non-pensionable supplement of 41% to offset superannuation contributions.

Further particulars and application form from The Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (468)

THE ROYAL FREE HOSPITAL HAMPSTEAD DEPARTMENT OF SURGERY

This Department now being established in the New Royal Free Hospital requires the following to participate in projects including studies of blood flow, organ preservation and transplantation, cryosurgery and liver surgery.

BIOPHYSICIST

Whose duties will include supervision and development of all physiological apparatus used in the research projects. Qualifications: Degree in Physics or other appropriate Science subject. Commencing salary £1,923 to £2,820 dependent upon qualifications and experience.

MEDICAL PHYSICS TECHNICIAN III

Whose duties will include maintenance and use of department research monitoring equipment including multichannel recorders, transducers and oscilloscopes, amongst other equipment. Qualifications: Appropriate Science Degree or HNC, ONC or HND. Salary: £1,845 to £2,337 depending on experience and qualifications.

Further details from the Professor of Surgery, The Royal Free Hospital, Pond Street, London NW3 2QG. Tel: 01-794 0500.

Application forms (to be returned by August 22) from the Assistant Personnel Officer 21 Pond Street, London NW3 2PN. Tel: 01-794 0431, Ext. 2. (493)

THAMES POLYTECHNIC SCHOOL OF BIOLOGICAL SCIENCES

Research Technician

Applications are invited for the post of research technician in the Division of Physiology and Cell Biology. The successful applicant will be expected to work with Dr. D. J. Beadle on the distribution of lysosomal enzymes in normal and virus-transformed cell lines. Experience in cell culture methods would be an advantage. The appointment will be for one year in the first instance with a salary of £1,478 per annum.

Further particulars and form of application may be obtained from the Secretary, Thames Polytechnic, Wellington Street, London, SE18 6PF, to whom completed applications should be returned by August 13, 1974. (498)

APPLIED SCIENTIST

The Radiochemical Centre is a leading World supplier of radioactive products many derived from reactors.

We have a vacancy for a qualified Scientist to join the Isotope Production Unit at Harwell. The work will involve the development of methods for the production and control of radioactive materials in high-flux reactors, and for their subsequent control and use.

The successful candidate should have a graduate level qualification in physics or engineering and a practical approach to problem solving. The salary will be at least £2,600 and is subject to a Threshold Agreement. Generous leave allowance and contributory superannuation scheme. Access to the staff canteen, social clubs and other facilities of the large UK AEA site at Harwell. Assistance with housing may be available.

For further details of the post dial 100 and ask the operator for FREE PHONE 3557 or write with brief details of career and qualifications to Mr. Martyn Bishop,

The Radiochemical Centre

Amersham

Bucks

GEOPHYSICIST

The Lamont-Doherty Geological Observatory of Columbia University announces a position with the seismology group as a Research Associate or Senior Research Associate. Candidates must have a strong background in seismic instrumentation and data analysis and will be expected to lead existing and initiate new programs of research involving observations of earth strain, tilt, and long-period seismic waves. Qualified candidates are invited to submit a resume of their qualifications, publications, names and addresses of three references by August 15, 1974. (460)

UNIVERSITY OF SURREY DEPARTMENT OF CHEMISTRY POSTDOCTORAL/POSTGRADUATE APPOINTMENT

Applications are invited for a post available from October 1, 1974 to work on the influence of iron salts on the products and mechanism of the nitrosation of organic compounds. Depending on the qualifications of the successful applicant, the appointment may be made at postdoctoral level, or at postgraduate level permitting study for a higher degree. A postdoctoral appointment would be made at the lowest point of the university lecturer scale with F.S.S.U., and a postgraduate appointment at S.R.C. rates (£695 plus fees). The minimum qualification for the latter appointment is a lower Second Class Honours Degree. Applications with a brief curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr L. F. Larworthy, Department of Chemistry, University of Surrey, Guildford, Surrey, GU2 5XH. (494)

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH DEPARTMENT OF BOTANY AND MICROBIOLOGY

RESEARCH ASSISTANT required for quantitative studies on growth and photosynthetic activity of individual leaves of plants during vegetative growth. Graduates in Botany, Agricultural Botany and related subjects, or Mathematics or Statistics considered. Appointment for one year, renewable up to three years.

Commencing salary: £830 per annum.

Further particulars and forms from the Registrar. (497)

THAMES POLYTECHNIC SCHOOL OF BIOLOGICAL SCIENCES DIVISION OF ENVIRONMENTAL BIOLOGY

Research Assistant

Applications are invited for a RESEARCH ASSISTANTSHIP in this Division to undertake studies on the microbial dissimilation of the halogenated phenoxyacetate herbicides.

Applicants should hold a good honours degree in Microbial Biochemistry, Biochemistry or Chemistry. Industrial experience and some training in Microbiology, are preferable though not essential.

The successful candidate will receive a starting salary of £1,544 per annum, plus payments under the threshold agreement, and will be expected to register for a higher degree.

Further particulars and form of application may be obtained from the Secretary, Thames Polytechnic, Wellington Street, London, SE18 6PF, to whom completed applications should be returned by August 20, 1974. (499)

Workshop Technician

Applications are invited for an experienced technician to service existing equipment and to help in the development and construction of new apparatus; applicants should hold an ONC or HNC or be an ex-Services Artificer and be familiar with electro-mechanical instruments for atmospheric sampling and for physiological measurement, as well as general laboratory apparatus; he should be able to work independently and would be expected to work on various materials and do his own machining and sheet metal fabrication and to work on instruments associated with a large exposure chamber and sampling sites away from the workshops. We offer 3 weeks and 3 days annual leave plus privilege and public holidays and salary according to age and experience rising to £2,451 per annum.

Applications to The Director, Medical Research Council Air Pollution Unit, St Bartholomew's Hospital Medical College, Charterhouse Square, London, EC1M 6BQ, Tel. No. 01-253 1537.

Medical Research Council

(510)

Bass Production Limited

A member of the Bass Charrington Group

require an

Analytical Chemist

The successful candidate will assume responsibility for analytical work in the Brewery. This key position involves the development of the analytical section, monitoring its performance, and managing a number of staff in a shift orientated department.

Although responsibility primarily will be of a routine nature, adaptability of approach will be sought, as continually developing production processes will require modification of existing methods.

Applicants must possess a degree in chemistry or equivalent qualifications and a knowledge of biochemistry would be an advantage. Management or supervisory experience in quality control laboratories in the brewing industry is equally important as formal qualifications.

The position offers a first class opportunity to acquire experience in the latest developments in brewing plant and production techniques.

In addition to an attractive salary and fringe benefits, help may possibly be given in certain cases for housing to be available in the Runcorn New town.

Please write giving brief details, of age and experience and present salary to:

**The Recruitment Manager,
Bass Production Limited,
Whitehouse Industrial Estate,
Runcorn, Cheshire**

(553)

Resource Economist FISHING INDUSTRY

As part of a general review of the fishing industry in the Northern Territory, the Dept. of the Northern Territory requires the services of a

Consultant Resource Economist

To examine data on existing and potential fish resources around the Northern Territory and to advise on future development strategies for the industry in the following situations:

- (a) Maximum development within a framework of specified controls, such controls to include current Northern Territory Legislation and Policy, together with other controls imposed on the industry by Australian Government policies in respect of Taxation, Immigration, Transport, Education, etc.
- (b) Unrestricted maximum development.

The Study is to be restricted to resources for which background information has been collated and does not extend to Aquaculture. In particular, the Consultant should be prepared to comment on:-

- Desirable rates of development to a given level of availability of particular resources.
- Management strategies to achieve these rates.
- Incentives if any, which may help achieve these rates or ultimate levels.
- The economic advantages or disadvantages of diversification within the fishery.
- Existing wage structures and modifications which may arise under guidelines proposed from the study.

Applicants should be prepared to commence study in 1974 for completion over a period of approximately three months, and it is expected that the successful applicant will spend an appropriate amount of time in the Northern Territory in consultation with local industry.

Further details including a synopsis of the fishing industry of the Northern Territory and a detailed list of all available source material are available from:-

The Executive Member, Northern Territory Fishing Industry Review Committee, P.O. Box 2783, Darwin Northern Territory, Australia 5794.

Applications should include appropriate personal details, summary of experience and any relevant publications, period available, together with full estimate of fees and costs including costs of travelling to Darwin in the Northern Territory of Australia, living expenses, Office accommodation and transportation.

Closing date: Friday 20th September 1974.

Address Proposals:
Assistant Director (Supply),
Department of the Northern Territory,
P.O. Box 4075,
Darwin Northern Territory, Australia 5794.

Telephone No: 819122
Telex Code NTASTOR 85062 Australia.

All enquiries will be accepted as potential proposals.

THE UNIVERSITY OF NEWCASTLE UPON TYNE CHAIR OF GEOGRAPHY

Applications are invited for the post of Professor of Geography. The vacancy arises as a result of the resignation from September 30, 1974, of Professor J. W. House, to take up the Halford Mackinder Professorship of Geography at the University of Oxford. Salary in accordance with the Professorial Scale (£5,973 by £96 to £6,069 by £195 to £6,849 per annum).

Further particulars may be obtained from the Registrar, the University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (15 copies), giving the names of not more than three referees, should be submitted not later than September 14, 1974. (495)

THE UNIVERSITY OF SHEFFIELD SENIOR LECTURER IN CHEMICAL PATHOLOGY

Applications are invited from medically or non-medically qualified persons for the above post, tenable from a date to be arranged. Research interests of the department include: peptide hormone interaction with cell receptors and subsequent cyclic nucleotide-mediated effects; secretion and action of parathyroid hormone; and certain aspects of the endocrinology of cancer. It is anticipated that the successful candidate will have a background in one of these areas or appropriate basic experience which could be applied. An appropriately qualified person may be considered for honorary consultant status by the Area Health Authority. Salary ranges (non-clinical) £4,707 to £5,844; (clinical without honorary consultant status) £4,917 to £6,213; (clinical with honorary consultant status) £5,085 to £7,599. Further particulars from the Registrar and Secretary, the University, Sheffield S10 2TN to whom applications (8 copies) should be sent by September 9, 1974. Please quote reference R 120/G. (500)

UNIVERSITY OF LEEDS DEPARTMENT OF PURE AND APPLIED ZOOLOGY

Applications are invited from graduates for a S.R.C. RESEARCH ASSISTANT-SHIP to work on the control of ventilation in dragonflies. This post is tenable for a period of up to three years from October 1, 1974. The starting salary will be £1,449 per annum. Applications should be sent to Dr. P. J. Mill, Department of Pure and Applied Zoology, University of Leeds, Leeds LS2 9JT, from whom further particulars may be obtained. Closing date August 17, 1974. (503)

UNIVERSITY OF HULL

A GRADE 4 RESEARCH TECHNICIAN is required for work in the Biomedical Unit. The successful applicant will help to set up a new laboratory and thereafter assist with: care of animals of various species; operative procedures; fixation of specimens; dissection and sectioning for gross anatomical study and optical and electron microscopy. Experience in the histology of central nervous tissue would be an advantage. The post is tenable for three years from October 1. Salary on scale £1,848 to £2,163 p.a. plus £104 p.a. threshold payment. Applications, giving details of age and experience and the names of two referees to the Technical Staff Officer, University of Hull, by Friday, August 9, 1974, quoting Ref. TBU/1. (501)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF BOTANY TECHNICIAN

Applications are invited for this new post. The successful candidate will be required to take special responsibility for the running and maintenance of the Department's research apparatus (and if possible help design and build new equipment), to organise and supervise the development, costing and preparation of undergraduate classes in physiology and biochemistry, and to deputise for the Chief Technician. The post offers plenty of scope for initiative.

Candidates should be qualified to H.N.C. or degree level in a Biological subject or chemistry. Salary within a range up to £2,874 per annum (plus threshold payments) according to qualifications and experience. Application forms which should be returned by September 1 may be obtained from The Registrar, The University, P.O. Box 147, Liverpool L69 3BX.

Quote ref RV/276150/N/

(502)

THE UNIVERSITY OF SHEFFIELD C.A.S.E. AWARD IN PHYSICAL CHEMISTRY OF MICELLES

Applications are invited from good honours graduates, or those about to graduate, in chemistry or chemical physics, for a CASE award under joint supervision of Dr I. A. McLure (the University of Sheffield) and Dr D. G. Hall (Unilever Research, Port Sunlight). Project will involve initially a study of distribution of suitable solutes between an aqueous solution of a surfactant and an immiscible and unsolubilized solvent with object of gaining improved understanding of nature of interior of micelles. Applications, (curriculum vitae and names of two referees) to Dr I. A. McLure, Department of Chemistry, The University, Sheffield S3 7HF, Tel. 78555 (S.T.D. 0742), from whom further details can be obtained. Please quote reference R119/G. (506)

Goldhawk Road, London W6 0XG

DEPARTMENT OF MICROBIOLOGY

Applications are invited from graduates with 1st or 2nd class Honours Degrees for the post of Senior Microbiologist (Terms and conditions of service Whitley Council A Scale, salary £2,964 p.a. to £3,843 p.a. plus £126 p.a. London Weighting plus threshold payments).

Applicants must have previous experience of medical microbiology.

Applications to the House Governor at the above address, naming three referees. (507)

THE GEOLOGICAL SURVEY OF GREENLAND

Geophysicist

A Geophysicist is required for the Geological Survey of Greenland. Candidates should have at least five years' experience in the various branches of exploration geophysics, particularly seismic interpretation, and should have a good command of English. The person appointed will be based in Copenhagen and will be required to plan and to participate in field projects in Greenland.

The appointment will be on renewable contract and will be pensionable. The salary will be according to Danish Government scales.

Applications should be accompanied by a detailed curriculum vitae, an indication of the approximate salary required, and the names of two referees, and should be sent before September 15 to: The Director, The Geological Survey of Greenland, Øster Voldgade 10, DK-1350 Copenhagen K, Denmark. (516)

RESEARCH OFFICER

Applications are invited for the post of Research Officer with the International Project in the Field of Food Irradiation, located in Karlsruhe, Federal Republic of Germany.

The successful candidate will be required to carry out research into the toxicological methodology of wholesomeness testing as applied to irradiated foods. The precise nature of the research will be determined according to the specific areas of expertise of the candidate selected for appointment who will assist in designing the research programme. Of particular interest to the Project are the problems associated with mutagenicity, carcinogenicity and teratogenicity testing.

Qualifications: Ph.D. or equivalent: several years of practical experience in toxicology or a closely related science. Fluency in English is essential and a working knowledge of German and/or French would be an advantage.

Conditions of service: The appointment will be on a yearly contract basis with the possibility of renewal, as a consultant to the Organisation for Economic Co-operation and Development. Salary, depending on qualifications and experience will be within the range US \$14,000 to \$19,000 net per annum (including expatriation and other allowances according to nationality and family circumstances).

Applications, accompanied by curriculum vitae to be made in writing by September 16, 1974 to the Project Director, International Food Irradiation Project, Institut für Strahlentechnologie, 75 Karlsruhe, Postfach 3640, Federal Republic of Germany. (514)

Wellcome

Research Scientist

This is an opportunity for a Ph.D or Good Honours Graduate with research experience in a biological discipline to join a new Research team being set up at The Wellcome Research Laboratories, Berkhamsted.

The work will involve the initiation of a research programme to investigate the effects of formulation and route of administration on absorption and distribution of drugs in animals.

We offer excellent conditions of employment, including help with re-location expenses where necessary, and real career prospects. Our laboratories are modern and well equipped, situated in pleasant countryside close to Berkhamsted, which is a small country town about 35 miles from Euston, London.

If you are interested please write or telephone for an application form quoting reference PA. 60, to:

**Mr. R. P. Woolridge, Senior Personnel Officer,
The Wellcome Foundation Limited,
Ravens Lane, Berkhamsted, Herts. HP4 2DY.
Tel: Berkhamsted 3333.**

(550)

ORGANIC CHEMIST

Industrial Research Chemist required for studies in synthetic chemistry.

Applicants should have First or Upper 2nd class Honours degree or equivalent, and preferably 1 - 2 years relevant experience. The assignment will be for 18 months in the first instance although the appointment is envisaged to be for at least five years, initially in the south-west of England. The salary will probably be in the

range of £2,500 to £3,000 p.a. according to qualifications and experience.

Reply, in confidence, with curriculum vitae, to Position Number ABO 651 Austin Knight Limited, Hagley House, Hagley Road, Birmingham B16 8QG.

Applications are forwarded to the Client concerned, therefore Companies in which you are not interested should be listed in a covering letter to the Position Number Supervisor.

AK ADVERTISING

UNIVERSITY OF DAR ES SALAAM—TANZANIA

Applications are invited for the following posts tenable as soon as possible:—

PROFESSOR IN PLANT BREEDING

Candidates should have considerable research and/or teaching experience in Plant Breeding and Genetics. The appointee will be required to lecture in some aspects of genetics and Plant Breeding to undergraduate and postgraduate students. He will be expected to plan, design and carry out with a team of breeders, selective plant breeding programmes. He should be able to apply advanced statistical and mathematical techniques for detailed genetic analysis and interpretation of results. He will also be required to collaborate with and advise other scientists in the Department.

ASSOCIATE PROFESSOR IN HORTICULTURE

Candidates should have a good honours degree in horticulture and postgraduate qualifications in horticulture or Crop Physiology. They should have considerable teaching and/or research experience in horticultural crops. The appointee will be expected to give lectures to undergraduate and postgraduate students in plantation crops, vegetable and ornamental crops. He will also be required to conduct research and supervise postgraduate students in his area of specialisation.

LECTURER/SENIOR LECTURER IN CROP PRODUCTION

Candidates should have at least an M.Sc. in Agronomy and some research experience and/or university teaching experience. Previous experience in tropical crops (field crops or plantation crops) would be an advantage. The appointee will be required to teach Annual Crops, Climatology, Weeds and Weed Control, to undergraduate and postgraduate students, and conduct research in his area of specialisation.

LECTURER/SENIOR LECTURER IN BIOMETRY

Candidates should have a good degree in mathematical statistics or Agriculture with postgraduate training in applied statistics and computer science. The appointee will be required to teach Biometry to undergraduate and postgraduate students. He will be expected to advise postgraduate students and academic staff in the Faculty on experimental designs, computer programming and utilisation and the interpretation of results.

LECTURER/SENIOR LECTURER IN PASTURE AGRONOMY

Candidates should have a good degree in Agriculture with postgraduate training and research experience in Pasture Agronomy. Experience in University teaching/research on pasture production in sub-tropical or tropical countries would be an advantage. The appointee will be expected to teach undergraduate students in various aspects of pasture production and range management. He will also be expected to undertake research on pastures.

RESEARCH FELLOW/SENIOR RESEARCH FELLOW IN PLANT BREEDING/AGRONOMY

Candidates for this post should be graduates in Agriculture or Botany with postgraduate training in Plant Breeding or Agronomy. Previous experience in Crop Production research would be an advantage. Appointee will be required to conduct research in the breeding or agronomic aspects of sorghum, millets or grain legumes—mainly soyabean, cowpeas, green and black grams.

Salary Scales: Professor TE3,332 to TE3,612 p.a.; Associate Professor TE3,052 to TE3,472 p.a.; Senior Lecturer/Senior Research Fellow TE2,632 to TE3,052 p.a.; Lecturer/Research Fellow TE2,150 to TE2,590 p.a. (TE1=£1.17 sterling). The British Government may supplement salary in range £996 to £2,448 p.a. (sterling) for married appointees or £348 to £1,500 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. F.S.S.U. Family passages; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail by August 27, 1974 to the Chief Academic Officer, University of Dar es Salaam, P.O. Box 35091, Dar es Salaam, Tanzania. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (539)

M.R.C. CLINICAL RESEARCH CENTRE

(Northwick Park Hospital)

Watford Road,

Harrow, Middlesex, HA1 3UJ

TECHNICIAN

required in the new Department of Surgical Oncology (Division of Surgical Sciences) to assist in a programme of research in human and experimental TUMOUR IMMUNOLOGY.

Familiarity with immunological procedures is desirable, including tissue culture, radiolabelling and cytotoxic reactions.

Salary within the range £1,566 to £2,418 plus Phase III Threshold Agreement increases.

Please contact Mrs. J. Tucker-Bull for further details quoting ref. 128/2. (513)

RESEARCH TECHNICIAN

(Grade 3)

required for work on fungal diseases in plants. Previous experience in this field or in biochemical techniques and electron microscopy is desirable but not essential.

Salary £1,650 to £1,920.

Apply: Senior Assistant Secretary, University of Birmingham, P.O. Box 363, Birmingham, B15 2TT. Reference 139/B/303. (522)

UNIVERSITY OF EDINBURGH DEPARTMENT OF CHEMISTRY

Applications are invited for a Post-doctoral Research Fellowship (S.R.C.) to study the synthesis and properties of cyclazines (annulenes containing internal nitrogen atoms) in collaboration with Dr. D. Leaver.

The appointment will be for two years from October 1, 1974 at a salary of up to £2,247 x £165 per annum with superannuation under F.S.S.U. depending on age and experience.

Applications, together with the name of an academic referee, should be sent to the Secretary to the University, University of Edinburgh Old College, South Bridge, Edinburgh EH8 9YL. Please quote reference number 5040. (517)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)

Keppel Street, WC1E 7HT

MEDICAL MYCOLOGY REFERENCE LABORATORY RESEARCH SCIENTIST

Applications are invited from postdoctoral Biochemists or Immunochemists for appointment, for five years initially, to work on an M.R.C. grant in this Laboratory run by the P.H.L.S. The successful candidate will direct research into the immunology of fungal diseases. Salary, depending on age, qualifications and experience, on scales rising to £2,694 (Post Probationary), £3,843 (Senior Scientific) or £5,175 (Principal Scientific), plus £126 London Weighting, and threshold awards. Superannuable post.

Applications in writing, giving full details of career etc. and naming two referees, should be sent to Dr D. W. R. Mackenzie, N. at the School, by September 30, 1974. (533)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF VETERINARY PATHOLOGY

LIVERPOOL AND WIRRAL

Applications are invited for the following posts:—

A. **TECHNICIAN** to work in the Liverpool diagnosis laboratory. Applicants should have experience in Bacteriology and Clinical Chemistry and hold H.N.C. Medical Science or equivalent I.M.L.T. certificate. Salary on a scale £1,680 to £1,920 per annum plus threshold payments. Quote ref. RV/N/276158(A).

B. **TECHNICIAN** to work in the Clinical Pathology Unit at the Veterinary Field Station, Leahurst, Neston, Wirral. The laboratory deals with bacteriological and parasitological diagnosis. Applicants must possess Intermediate I.M.L.T. or O.N.C. Medical Sciences. Salary on the scale £1,524 to £1,794 per annum plus threshold payments. Quote ref. RV/N/276158(B).

Initial salary will be according to qualifications and experience. Application forms for both posts may be obtained from The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. (557)

Toxicologist

We require a Toxicologist in the Department of Toxicology to participate in the evaluation of new medical substances for possible toxicological and teratogenic potential.

Applicants should have graduated in a biological subject or possess a Higher National Certificate or Diploma in Applied Biology with appropriate experience: a new graduate will be considered.

Please Apply to:

Mrs J. Andrews,
Personnel Officer,

John Wyeth & Brother Ltd,
Huntercombe Lane South, Taplow,
Nr. Maidenhead, Berks BL6 0PH
Telephone Slough 28311.

Wyeth

(569)

**UNIVERSITY OF EDINBURGH
FACULTY OF MEDICINE
ON-LINE BIBLIOGRAPHICAL
RETRIEVAL PROJECT IN
BIOMEDICINE**

Applications are invited for the post of RESEARCH ASSISTANT to work with the Lecturer in Medical Information on the above project, financed by the British Library Research and Development (formerly O.S.T.I.). The systems principally involved will be those of the two MEDLARS on-line retrieval systems, MEDUSA and MEDLINE. The person appointed will act as intermediary between customers and systems in on-line formulation and evaluation.

Applicants should be graduates in a science subject, and information science/library qualifications or experience would be an advantage.

The salary will be £2,118 per annum plus F.S.S.U.

The post is available from October 1, and will extend to December, 1975.

Further particulars from Dr E. D. Whittle, University of Edinburgh Medical School, Teviot Place, Edinburgh, EH8 9AG, to whom applications, together with the names of two referees, should be sent by August 12, 1974. Please quote reference number 5039. (519)

UNIVERSITY OF LEICESTER

Applications are invited for the posts of laboratory technician Grade 3(i) and Grade 4(i) in the Department of Physiology.

The Grade 3 post will mainly involve research work into membrane transport and associated topics, also to assist with some practical classes. Applicants should have H.N.C./H.N.D. or equivalent qualifications and have had 3 to 5 years laboratory experience.

The Grade 4 post will be for organisation of practical classes for medical students and will involve the use of up-to-date electro-physiological equipment and therefore requires a knowledge of equivalent qualifications and have had 7 to 9 years laboratory experience.

Salary scales are Grade 3 £1,650 to £1,920, and tronic. Applicants should have H.N.C./H.N.D. or Grade 4 £1,848 to £2,163 plus cost-of-living supplements.

Applications giving full details of educational background, qualifications and experience together with the names and addresses of two referees should be sent as soon as possible to the Chief Technician, Department of Physiology, University of Leicester LE1 7RH. (565)

**UNIVERSITY OF EDINBURGH
DEPARTMENT OF PHYSICS**

Applications are invited for a vacant post of University Demonstrator in the above Department. Teaching duties (laboratory and tutorial work) will not normally exceed 10 hours per week. The successful candidate will be expected to register for a higher degree, if he does not already hold one. Details of research in progress can be obtained on application to the Department.

The appointment is renewable annually up to a maximum tenure of five years, and will be according to qualifications and experience on the scale £1,848 to £2,538 per annum. Superannuation under F.S.S.U.

Applications, by letter, giving full details together with the names of two referees, should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL, not later than September 13, 1974. Please quote reference number 1036. (518)

**UNIVERSITY COLLEGE GALWAY
Professorship of
Experimental Physics**

Applications are invited for the above statutory whole-time post. Salary scale £5,427 x 141 (8) to £6,555, plus Family Allowances. Non-contributory Pension Scheme.

The closing date for receipt of applications is **September 16, 1974**. Prior to application, further information should be obtained from the Registrar of the College. (562)

entomologists

We wish to recruit two Entomologists. Applicants should hold a degree in Biological Sciences specialising in Entomology, and have subsequent experience in either:

(a) the field evaluation of new insecticides or related products and their establishment on the market. For preference the experience should relate to Mediterranean and tropical crops. The person appointed will be expected to travel up to four months of the year in periods of a few weeks at a time.

(b) The evaluation of new insecticides in the laboratory. Applicants with experience in studying the way insecticides act at the whole insect level will be preferred. A knowledge of insecticide chemistry is desirable, together with an acquaintance with the opportunities for new products gained from experience in the field.

**PLANT PHYSIOLOGIST/
GENETICIST**

We have a vacancy for a Technical Officer to initiate a new programme of work on the effect of chemicals on the development and fertility of flowers of important crop species. The work will be particularly directed towards the discovery of chemicals which may assist

in the development of hybrid varieties.

The person appointed will be based at Jealott's Hill Research Station where extensive modern laboratory glasshouse and growth chambers are available. He may, however, be required to spend periods overseas in order to carry out necessary experimental work, supporting technical staff will be available.

Qualifications: Degree in Botany or Agriculture or allied subject preferably with a Ph.D. in Plant Physiology or physiological aspects of genetics. Previous work on the effects of chemicals on plant development or on the production of hybrid varieties would be an advantage.

Salaries will be dependent on qualifications and experience. Fringe benefits include membership of the ICI Pension and Profit Sharing schemes.

After joining married men will receive a reasonable refund of removal (including travel) expenses and, in approved cases, assistance in house purchase. If you are interested in applying please write for an application form to:

**Mr S. R. Stephenson,
Personnel Officer,
ICI Plant Protection Ltd.,
Jealott's Hill Research Station,
BRACKNELL, Berks (555)**

PLANT PROTECTION LIMITED

UNIVERSITY OF DAR ES SALAAM — TANZANIA

Applications are invited for the following posts tenable as soon as possible:—

LECTURER/RESEARCH FELLOW IN CHEMISTRY (Organic). Candidates must be holders of Ph.D. or its equivalent in Organic Chemistry and should be capable of teaching all aspects of Organic Chemistry to undergraduate level students. The appointee will also be expected to teach and supervise at postgraduate level. Research interests in natural products will be an advantage but not essential. An applicant who would like to do more research and only a limited amount of teaching may be considered for appointment as Research Fellow.

LECTURER/SENIOR LECTURER IN MARINE BIOLOGY. Candidates should have a Ph.D. degree in appropriate subjects. Preference will be given to those with teaching experience in aquaculture or ichthyology. The appointee will be attached to the Marine Biology Station, under the Department of Zoology of the University and will be required to participate in team-work research mainly in marine ecology, to supervise postgraduate students in Marine Biology, and to participate in the teaching of undergraduate students in the Department of Zoology.

Salary Scales: Senior Lecturer T£2,632-T£3,052 p.a.; Lecturer/Research fellow T£2,150-T£2,590 p.a. (T£1 = £1.17 sterling). The British Government may supplement salary in range £996-£1,848 p.a. (sterling) for married appointees or £348-£900 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. FSSU. Family passages; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail by August 27 1974 to the Chief Academic Officer, University of Dar es Salaam, PO Box 35091, Dar es Salaam, Tanzania. Applicants resident in UK should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars may be obtained from either address. (538)

YORKSHIRE WATER AUTHORITY SCIENTISTS

The work of the Authority extends over an area which coincides very closely to the geographical boundaries of Yorkshire.

Vacancies have now arisen in the Scientific Services section which carries out works in most aspects of the Authority's activities. First class staff are required for the following work in Leeds.

BACTERIOLOGIST — £3,504 to £3,993 plus Threshold Payment. RN 46. The vacancy exists in a small group which is undertaking specialised bacteriological investigations, identifying the virological problems in the Authority's area and giving bacteriological advice to Divisions. Applicants should be graduates with a degree and experience relevant to this area of work.

SCIENTIFIC AND TECHNICAL OFFICER FISHERY SCIENCE — £2,394 to £3,018 plus Threshold Payment.

RN 58. This post is located in Scientific Services at Head Office, Leeds and heads a small team of Fishery Scientists. The duties will involve investigations into causes of fish mortalities, fish population studies and fishery management advice.

With the agreement of the Water Services Staff Commission these posts are not restricted to staff within the Water Industry, although first consideration will be given to applicants so employed.

Applications quoting the appropriate reference number and giving details of age, qualifications, salary and experience should be sent to the Personnel Officer, Yorkshire Water Authority, West Riding House, 67 Albion Street, Leeds LS1 5AA by August 12, 1974.

(568)

YORKSHIRE WATER AUTHORITY

UNIVERSITY COLLEGE LONDON DEPARTMENT OF ANATOMY

RESEARCH ASSISTANTS (2), preferably post-doctoral, required to work on ultrastructural studies of synaptic organisation in vertebrate C.N.S. with Drs K. E. Webster and A. R. Lieberman. Appointment October 1, 1974 or as soon as possible thereafter for a period of up to 3 years. Starting salary up to £2,118 plus £213 London Allowance. Curriculum Vitae and names of two referees, as soon as possible to Dr Webster and Dr Lieberman, Dept. of Anatomy, (N) University College London, Gower Street, WC1E 6BT. (534)

M.R.C. RHEUMATISM UNIT CANADIAN RED CROSS MEMORIAL HOSPITAL TAPLOW, NR. MAIDENHEAD, BERKS.

IMMUNOLOGY

Technician required to take part in immunological research in rheumatism and connective tissue disease.

Modern immunological laboratory procedures are in everyday use, including immunofluorescence, immunoperoxidase and radioisotope methods.

The successful applicant will be offered training in these as required. The post offers excellent opportunities to work for higher qualifications, IMLT or equivalent qualification required.

Applications, with the names of two referees, to the Director, M.R.C. Rheumatism Unit, at the above Hospital. (531)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF DERMATOLOGY RESEARCH STUDENTSHIP

Applications are invited from graduates with an Honours Degree in Biochemistry for a Junior Research Associate appointment to work on research on androgen metabolism in the skin. Candidates should have an interest in steroid biochemistry. The appointment will be for one year in the first instance but renewable up to a maximum of three years in all and the post will be suitable for a student who wishes to study for a higher degree. Allowances equivalent to those in the case of M.R.C. Studentships will be paid.

Applications should be sent as soon as possible to Professor S. Shuster, Department of Dermatology, Royal Victoria Infirmary, Newcastle upon Tyne, NE1 7RU. (524)

MURDOCH UNIVERSITY Western Australia

SCHOOL OF VETERINARY STUDIES

Applications are invited for several positions in each of the following fields within the Division of Veterinary Biology. Candidates should be capable of relating structural and functional features of domestic animals. They would normally be expected to have a higher degree.

ANATOMY/HISTOLOGY PHYSIOLOGY

BIOCHEMISTRY/NUTRITION

Duties include: **TEACHING**: participation in the first part of the veterinary biology programme leading to an understanding of the animal body. It starts with concurrent themes on the **BODY AS A WHOLE** and **CELL BIOLOGY** followed by an integrated study of **BODY SYSTEMS**. **RESEARCH**: candidates will be expected to have an active research interest either in general cell biology or in one or more of the body systems.

Level of appointment: One of the Anatomy/Histology vacancies is at a senior level. The other appointments will be in the scales of Lecturer or Senior Lecturer. Present salary scales are: Lecturer \$A9,002 to \$A12,352; Senior Lecturer \$12,643 to \$A16,724; Associate Professor \$A16,389.

General Information: 48 veterinary students will enter this phase of the course in March 1976. The Head of the Veterinary School is Professor R. H. Dunlop; The Chairman of the Division of Veterinary Biology will be Dr J. McC. Howell, presently at the University of Liverpool; The Chair in Physiology will be filled by Dr R. G. Wales, presently at Sydney University, who will coordinate the study of the animal body. Appointments are available to commence at various times during 1975.

•Further information is available from the Secretary, Murdoch University, Murdoch, Western Australia 6153 or from the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. (526)

Applications close on September 30, 1974. (526)

Agricultural Chemicals Development

May & Baker Ltd. wish to recruit staff for two new posts in their Agricultural Development Division at Ongar Research Station, Essex.

DEVELOPMENT OFFICER

This Officer will assist the Chief Development Officer in the planning and co-ordination of programmes for the evaluation of agricultural products throughout the world. The successful candidate, male or female, will be responsible for the collection and dissemination of technical data between the Research Station and the Company's Branches and Agents.

Applicants, between the ages of 24 and 30, should have a Degree, preferably with a science as a main subject, and should have a working knowledge of French, German or Spanish. Experience in the pesticides industry, in the fields of technical information or publications, would be an added advantage, and the candidates should have the ability to summarise technical data and to express themselves lucidly in English.

RESEARCH SCIENTIST

He will lead a small team of biologists and will be responsible for all programmes on the field evaluation of herbicides in the U.K. and overseas.

Candidates, between the ages of 28 and 35, should possess an Hons. Degree or M.Sc., in Botany with some specialisation in weed control. They should also have some experience in Research and Development in the pesticide industry.

Reference No. 185/N/1

Reference No. 186/N/1

May & Baker provide first class conditions of employment including a competitive starting salary and contributory pension scheme with free life assurance cover. Assistance towards removal expenses will be considered in suitable cases.

Please apply in writing quoting the appropriate reference number giving details of qualifications and experience to the Personnel Manager, May & Baker Ltd., Dagenham, Essex RM10 7XS. (512)

M&B May & Baker

ROYAL COLLEGE OF
SURGEONS IN IRELAND
DIVISION OF BIOCHEMISTRY

Junior Lecturer

Applications are invited for the above post.
Salary £2,180 plus £134 (4) to £2,716, point of entry to be determined by qualifications and experience.

Preference will be given to applicants with an interest in one of the following fields: Developmental Biology; Brain Biochemistry; Clinical Research.

Applications giving the names of two referees should be received not later than Monday, September 9, 1974.

Further particulars from the Registrar, Royal College of Surgeons in Ireland, Saint Stephen's Green, Dublin 2. (532)

UNIVERSITY KONSTANZ
(WEST GERMANY)

RESEARCH POSITION FOR
ELECTROPHYSIOLOGIST

Applications are invited for a postdoctoral position to electrophysiological investigations of normal and transformed cell cultures in vitro. This work is part of a research project on regulation of cell division sponsored by Deutsche Forschungsgemeinschaft.

Please send your application, curriculum vitae including details of your previous experience to: Sonderforschungsbereich 138, Biologische Grenzflächen und Spezifität, der Universität Konstanz, D-775 Konstanz, Postfach 733. (520)

UNIVERSITY OF SYDNEY
LECTURESHIP/SENIOR
LECTURESHIP IN
AGRICULTURAL GENETICS

Applications are invited for the above-mentioned position in the Plant Breeding Institute of the Department of Agricultural Botany. We are especially interested in persons who have had research and teaching experience in the cytology and cytogenetics of agricultural crops. The person appointed will be expected to teach courses in general genetics and in cytogenetics to third and fourth year students. He will also be expected to supervise postgraduate students and to participate in some phase of crop improvement in association with the University Plant Breeding Institute.

The position advertised is permanent, but the lectureship may be filled for three years in the first instance with possibility of permanency after that time, or in certain cases return fares.

Salary range: Lectureship: \$A9,002 to \$A12,352 p.a. Senior Lectureship \$A12,643 to \$A14,724 p.a.

Applications, including details of qualifications and experience and names of two referees, by August 19, 1974 to the Registrar, University of Sydney, New South Wales 2006, Australia. Information also available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (527)

Research in
Instrumentation and
Control Engineering

Applications are invited from graduates with good honours degrees in Physics, Engineering or Mathematics for two posts:

(1) CONTROL AND INSTABILITY OF FLUID DISTRIBUTION SYSTEMS

(2) CORRELATION TECHNIQUES OF FLOW MEASUREMENT

Candidates will register for a higher degree with the CNAA.

Salary: one post £1,500-2x£81-£1,662.

one post SRC Studentship supplemented by some Tutorial work.

Further details and application form from Staffing Section, Department N, Teesside Polytechnic, Middlesbrough, Cleveland TS1 3BA. (537)

Senior Information Scientist (£4550-£5900)

This post, initially based in London will provide a service to all Ministry of Agriculture, Fisheries and Food R & D laboratories, and to its Agricultural Development and Advisory Service throughout the country.

The scientific information field in the Department is extensive and complex, with a variable level of indexing, abstracting and information retrieval in the many relevant disciplines and at a number of levels for the different areas it serves.

Major responsibilities will be to review the existing scientific and technical information systems in the light of the latest advances in information science; to advise on the introduction of new systems; and to liaise with other Departments and non-Government organisations concerned with the storage, retrieval and dissemination of information with special reference to agriculture and allied subjects.

Candidates should normally hold a 1st or 2nd class honours degree in a scientific subject (including information science). Considerable relevant experience at responsible levels is necessary; experience in organising and developing scientific information systems is essential.

Appointment will be as Principal Scientific Officer, with starting salary within the range quoted, and may be permanent and pensionable or, with present employer's agreement, on secondment terms.

For further details and an application form (to be returned by 23 August 1974) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone BASINGSTOKE 29222 extension 500 or LONDON 01-839 1992 (24 hour answering service). Please quote reference S/8714/3.

A NEW POST IN MINISTRY OF AGRICULTURE, FISHERIES AND FOOD.

(587)

ROYAL PAVILION
ART GALLERY AND MUSEUMS
BRIGHTON

Applications are invited for the following three new posts:

(1) KEEPER OF BIOLOGY
(ref. BM1)

Salary A.P. 4/5 (£2,235 to £2,820), plus current Threshold payment.

(2) KEEPER OF GEOLOGY
(ref. BM2)

Salary A.P. 4/5 (£2,235 to £2,820), plus current Threshold payment.

Applicants should have an appropriate University degree; possession of the Museums Association diploma would be an advantage. Relevant experience is desirable.

Full details of the posts may be obtained from The Director, The Royal Pavilion, Brighton, BN1 1UE, quoting appropriate post reference. Written applications, giving full details, together with names and addresses of two referees, should be received by August 21, 1974. (511)

PRE- or POST-DOCTORAL
BIOCHEMIST

with at least 4 years post-graduate experience, especially in protein fractionation and immunochemistry, required for research in relation to M.R.C. trials in myeloma and macroglobulinaemia for at least two years from October 1, 1974. Salary equivalent to Senior Biochemist, (from £3,090 p.a.). Applications with two referees to Prof. J. R. Hobbs, Department of Chemical Pathology, Westminster Medical School, 17 Page St., London SW1 by September 9, 1974. (551)

EDITORIAL ASSISTANT

A microbiologist with a good knowledge of French and a zoologist with a good knowledge of German are invited to join the Editorial Team of Information Retrieval Limited, a publisher of scientific literature. Starting salary is £2,108 per annum. Please apply to: Dr. E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London W1V 5FG. (563)

UNIVERSITY OF SYDNEY
LECTURESHIP IN AGRONOMY
(CROP BOTANY)

Graduate in Science or Agricultural Science, with Ph.D. or equivalent experience in crop botany. Applicants should have wide experience with Australian Crop plants, including field crops, horticultural crops and pasture species.

The position advertised is permanent but may be filled for three years in the first instance with possibility of renewal after that date, or in certain cases return fares.

Salary range: \$A9,002 to \$A12,352 p.a.

Applications, including curriculum vitae, list of publications and names of three referees, by September 3, 1974 to the Registrar, University of Sydney, NSW 2006, Australia, from whom further information available. Information also available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (528)

DEPARTMENT OF
BIOCHEMISTRY

Applications are invited for the vacancy of Postdoctoral Research Assistant in the Department of Biochemistry, to work on an S.R.C. sponsored research programme concerned with the occurrence, metabolism and function of 3':5'-cyclic A.M.P. in the tissues of higher plants.

The appointment, which will be for one year in the first instance, from October 1, 1974, will be on the scale £2,118 to £2,757 per annum, together with F.S.S.U. benefits.

Further particulars and application forms (2 copies) may be obtained from the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to whom they should be returned by Friday, August 23, 1974. (542)

Thinking ahead
in
Pharmaceuticals

Young Science Graduate for teratological work

We are a major pharmaceutical company and part of the £multi-million international Glaxo Group. Our modern research laboratories are located in pleasant rural surroundings at Ware in Hertfordshire.

We have an interesting opportunity for a recently qualified science graduate to work on the teratological aspects of drug safety evaluation. This position will involve supervising the work of a small section in the Pathology Department and taking part in all aspects of investigations.

Salary and conditions are attractive and include assistance with relocation expenses, where appropriate.

Please write, with brief career details, to:

Glyn Jones,
Personnel Officer,
Allen & Hanburys Research Ltd.,
Priory St., Ware, Herts. SG12 0DJ.

Allen & Hanburys MAKERS OF FINE PHARMACEUTICALS

NATURAL ENVIRONMENT RESEARCH COUNCIL

INSTITUTE OF GEOLOGICAL SCIENCES ANALYTICAL CHEMIST

A vacancy exists at Scientific Officer/Higher Scientific Officer level in the Institute's Hydrogeology Unit in London. Appointment will be on a permanent established basis.

Duties: To work with a small group engaged in research and applied studies concerned with various aspects of natural waters, and based in the Hydrogeological Department. Responsibilities will consist of management of the laboratory, direction of routine analysis and development of new techniques, particularly for trace analysis.

Qualifications: Candidates will be expected to have a Good Honours Degree in Chemistry, or equivalent qualification. Previous analytical training or experience relevant to geochemical/environmental analysis is desirable: familiarity with flame atomic absorption is required and knowledge of flameless techniques and gas-liquid chromatography would be an advantage. Candidates at H.S.O. level should have at least 2 years relevant postgraduate experience.

Salary: Scientific Officer, £1,820 to £2,903; Higher Scientific Officer, £2,689 to £3,599, inclusive of Inner London Weighting.

Starting salaries may be above the minimum.

The staff of the Council are not Civil Servants although their pay and conditions of service are similar to those of scientists in the Civil Service.

Application forms available from Establishment Section, Institute of Geological Sciences, Exhibition Road, London SW7 2DE, quoting ref: SO/HYD/74/3.

CLOSING DATE FOR RECEIPT OF APPLICATION FORMS AUGUST 16, 1974. (560)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING (University of Reading)

A Scientific Officer or Higher Scientific Officer is required to join a group in the Bacteriology Department investigating the intestinal microflora of the neonate with particular reference to the antibacterial activity of milk. Experience with immunological techniques will be an advantage.

Candidates should have a degree, H.N.C. or equivalent qualification. Appointment will be in the grade of Scientific Officer (£1,592 to £2,675) or Higher Scientific Officer (£2,461 to £3,371), with a starting point dependent on qualifications and experience. At least five years' relevant post-qualifying experience is required for appointment in the higher grade. The post is pensionable.

Apply on forms obtainable from the Secretary, National Institute for Research in Dairying, Shinfield, Reading RG2 9AT, quoting reference 74/17. (561)

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH DEPARTMENT OF PHYSICS

Applications are invited for the posts of:
**RESEARCH ASSOCIATE or
RESEARCH OFFICER**

to work under the following S.R.C. sponsored projects:

1. Ion-Molecular Collisions of ionospheric interest using a temperature-variable afterglow system.
2. Rocket-borne measurements of minority neutral constituents in the D-region of the ionosphere.

Salary range: Research Associate, £2,118 to £2,580 p.a.; Research Officer, £1,662 to £2,550 p.a.

Further details and forms obtainable from Professor N. D. Twiddy, Department of Physics, Penglais, Aberystwyth. (566)

MASSEY UNIVERSITY Palmerston North, New Zealand BIOTECHNOLOGY DEPARTMENT SENIOR LECTURESHIP - BIOCHEMICAL ENGINEERING

Applications are invited for positions of Senior Lecturer, in the Biotechnology Department, concerned with the application of chemical and biochemical engineering to fermentation technology and industrial biological processing. The background sought ideally would include a degree in chemical engineering, Ph.D. or equivalent in biochemical engineering, and industrial experience.

Salary: in the range NZ\$9,503 to \$11,153 (bar) to \$12,142.

Further details may be obtained from the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Application close on **September 9, 1974.**

(583)

UNIVERSITY OF STRATHCLYDE DEPARTMENT OF FOOD SCIENCE AND NUTRITION

RESEARCH FELLOWSHIP

Applications are invited from post-graduates in biochemistry, biological chemistry or molecular biology for the above appointment.

The appointee will be a member of a team investigating the mechanisms of fluorochrome reactions with micro-organisms.

The appointment will be for three years on the salary scale £2,118 to £2,412 per annum with F.S.S.U.

Applications (quoting R28/84) containing the names of two referees, should be sent to Dr. J. Scholefield, Department of Food Science and Nutrition, University of Strathclyde, James P. Todd Building, 131 Albion Street, Glasgow G1 1SD. (530)

UNIVERSITY OF WAIKATO HAMILTON, NEW ZEALAND LECTURERS/SENIOR LECTURERS

The University invites applications for academic positions that will be available from February 1, 1975. The positions which are listed below will be at lecturer or senior lecturer level. The reference numbers for each vacancy are given in brackets.

BIOCHEMIST

(203) with interests in biological chemistry or one of the branches of biology.

BIOLOGICAL SCIENTISTS

(204) cellular biologist with interests in microbial genetics or physiology or virology or cell physiology —(205A) zoologist with interests in invertebrate physiology or vertebrate biology or physiology or animal behaviour—or (205B) plant ecologist.

CHEMISTS

(206) (207) preferred interests in one or more of physical chemistry, natural products or biological chemistry, spectroscopic methods.

COMPUTER SCIENTISTS

specialising in (208) computing machines and communication systems and (209) management data processing and information systems.

GEOGRAPHER

(216) human geographer specialising in quantitative

MATHEMATICIAN

(222) statistics or computing, preferably with experience in design of experiments or sampling for scientific or technological applicants.

PSYCHOLOGISTS

(preferably with cross cultural interests in each case) (224) applied social psychology including measurement (225) clinical psychology (226) interests in research and natural settings including animal behaviour.

The current salary scales run from NZ\$7,361 to NZ\$9,339 per annum for lecturers and NZ\$9,503 to NZ\$11,153 to NZ\$12,142 per annum for senior lecturers.

Applications close on **September 13, 1974** and should be submitted in a prescribed format.

Details and conditions of appointment are available from the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, University of Waikato, Hamilton, New Zealand. (559)

Chemical or Biochemical Engineer and Fermentation Technicians for Fermentation Research and Development

Shell Research Limited have vacancies for one scientist (Chemical or Biochemical Engineer) and four technicians to work in a multi-disciplinary team in the Fermentation Division of their Woodstock Laboratory, Sittingbourne, Kent.

Chemical or Biochemical Engineer

You will join a team concerned with new fermentation projects based on hydrocarbon and petrochemical feedstocks. You should have a good degree in Chemical Engineering and a minimum of three years' research and/or development experience. Ability to furnish evidence of significant contributions to fermentation or other biological processes would be an advantage.

Fermentation Technicians

You will carry out development work concerned with the production of single-cell protein from methane. You should have experience in fermentation processes and be in possession of an HNC or equivalent in Chemical Engineering, Biochemical Engineering or Applied Biology. Experience in pilot plant fermenter and process equipment operation would be an advantage.

The level of appointment will depend on background and experience and the salary offered will be competitive. There is an excellent pension scheme, a good staff restaurant and sports/social facilities are provided. Please write, indicating which position you wish to apply for, giving full details of personal background and experience to:— Shell Research Limited, Recruitment Division (N), PNE/34, Shell Centre, London SE17NA.

UNIVERSITY OF SIERRA LEONE FOURAH BAY COLLEGE

Applications are invited for the following posts:-

1. **SENIOR LECTURER/LECTURER IN BOTANY**, tenable as soon as possible. Applicants should have a good honours degree and post-graduate research experience, preferably in Plant Morphogenesis or Plant Anatomy, but applicants in other fields will be considered. Teaching duties will include participation in elementary courses in Biology and Botany and other courses according to the qualifications and interests of the appointee and the needs of the Department. He will also be expected to carry out research in his specialist field.

2. **LECTURER IN PHYSICS**. Research interests in Geophysics or Theoretical Physics would be considered an additional advantage.

Salary scales (under review): Senior Lecturer Le4,550 to Le5,400 p.a.; Lecturer Le2,400 to Le4,740 p.a. (£1 sterling = Le2). The British Expatriates Supplementation Scheme is unlikely to be applied to these appointments. F.S.S.U. Family passages; various allowances; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than September 2, 1974 to the Secretary, University of Sierra Leone, Private Mail Bag, Freetown, Sierra Leone. Applicants resident in the U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars may be obtained from either address. (571)

SUB-EDITOR

BUTTERWORTH'S, who publish a wide range of scientific titles, are looking for a sub-editor to assist in the publication of the International Union of Pure and Applied Chemistry (I.U.P.A.C.) series. Previous editorial experience is required, as is a specialist knowledge of organic chemistry.

The offices are situated in pleasant rural surroundings at Borough Green, near Sevenoaks, Kent and company transport is available from certain surrounding districts.

Salary according to N.U.J. scale.

Please write, giving details of age, qualifications and experience to:

Mr F. Langton,
Butterworth & Co. (Publishers) Ltd.,
Borough Green,
Nr. Sevenoaks,
Kent.

(574)

Imperial College

A Postdoctoral Research Assistant is required in the Metal Physics group for experimental work on the Super-Conducting Proximity Effects. Candidates should have a Ph.D. or confidently expect to obtain one shortly, and should have experience of work at low temperatures. Familiarity with Super-Conductivity and Radio-Frequency techniques would be an advantage. The appointment will be for a maximum of three years beginning October 1, 1974.

The starting salary will be £2,118 plus £213 London Allowance and Threshold Payment with F.S.S.U. Curriculum vitae and the names of at least two referees should be sent as soon as possible to:-

Dr J. G. Park
Department of Physics
Imperial College
London SW7 2BZ
Tel 01 589 5111 Ext. 2303

(570)

HERIOT-WATT UNIVERSITY DEPARTMENT OF CHEMISTRY RESEARCH TECHNICIAN

to work on the synthesis and reactions of new penicillins. Applicants should have appropriate qualifications for synthetic organic chemistry.

Salary up to £1,704 by £54 to £1,812 p.a.

Applications, together with curriculum vitae and names of two referees to Dr M. M. Campbell, Department of Chemistry, Heriot-Watt University, Riccarton, Currie, Midlothian. (576)

UNIVERSITY OF MALAWI CHANCELLOR COLLEGE

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN BIOLOGY (PLANT PHYSIOLOGY), tenable as soon as possible. Candidates should have a higher degree, preferably a Ph.D. and some teaching experience in Plant Physiology. An interest in applied Plant Physiology and Biochemistry is required. Appointee will be required to teach Plant Physiology to 3rd and 4th Year degree students and assist with elementary work in 1st and 2nd Year. Salary scales (including expatriate addition): (a) K5,242 to K5,881 p.a. (b) K2,809 to K4,714 p.a. plus either a University Addition of K720 p.a. (taxable in Malawi) or the British Government may supplement salary in range £600 to £1,080 p.a. (sterling) for married appointee or £300 to £800 p.a. (sterling) for single appointee (normally free of all tax) and provide children's education allowances and holiday visit passages. (£ sterling = K1.99). Gratuity of 15% to 25%; superannuation scheme transferable with F.S.S.U.; family passages; various allowances; biennial overseas leave; housing. Detailed applications (2 copies) including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than September 2, 1974 to the Registrar, University of Malawi, University Office, P.O. Box 278, Zomba, Malawi. Applicants by airmail, not later than September 2, 1974 to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (572)

THE UNIVERSITY OF ADELAIDE invites applications for four appointments as LECTURER IN ZOOLOGY

Applications will be welcomed from persons with interests and expertise in one or more of the following fields: educational innovation at the tertiary level; ecophysiology of aquatic animals—freshwater or marine; ethology; parasitology. Applicants with experience in tertiary teaching and with interests in other fields may be considered. It is desired that successful applicants be able to take up their positions early in January 1975.

SALARY SCALE: \$A9,002 by 479 (4) by 478 (3) to \$A12,352; with superannuation on the F.S.S.U. basis.

FURTHER INFORMATION, including list of particulars required in an application, is available from the Registrar of the University or from the Secretary-General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London, WC1H 0PF.

APPLICATIONS should reach the Registrar, G.P.O. Box 498, Adelaide, South Australia 5001, not later than August 23, 1974. (580)

(588)

Lister Institute of Preventive Medicine
ELSTREE, HERTFORDSHIRE
BLOOD PRODUCTS
LABORATORY

Recent graduate required for bacteriological work in connection with human blood products and to assist in research and development. Possible registration for higher degree for appropriate applicant with first or upper second class honours degree. Please apply stating qualifications, age and experience to: The Secretary (Ref: BP), Lister Institute of Preventive Medicine, Elstree, Herts., from whom further particulars can be obtained.

(579)

NATIONAL INSTITUTE FOR MEDICAL RESEARCH
MILL HILL — LONDON

ELECTRON MICROSCOPY TECHNICIAN required, familiar with thin tissue sectioning, to assist in the examination of cells and sub-cellular components during animal development. Experience in electron microscopy would be an advantage. Initial salary, according to age, qualifications and experience, will be on scales £1,683 to £2,577 p.a. or £2,346 to £3,147 p.a. Please write, quoting ref. EM/DB/BL, to J. H. Woodcock, Personnel Officer, National Institute for Medical Research, The Ridgeway, Mill Hill, NW7 1AA, Tel: 959-3666 giving details of age, experience and qualifications

(575)

PORTSMOUTH POLYTECHNIC
BIOPHYSICS LABORATORIES

Two posts of Research Assistant are available in the above laboratories to join a large research team under Dr E. M. Bradbury, working on the problem of the structure of the chromosome. A wide range of physical and biochemical techniques are employed, including X-ray and neutron diffraction, electron microscopy, gel filtration and ultracentrifugation. The successful candidate will probably have an honours degree in either chemistry, biochemistry or physics, together with a lively interest in the control of fundamental biological processes at the molecular level.

The appointments will be for a period of three years and registration for a higher degree is expected.

Salary scale: £1,320 to £1,420 per annum. A threshold payment currently £10.44 per month is also payable.

Application forms and further particulars may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth, PO1 2QQ, within 10 days of the publication of this advertisement. (573)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF ASTRONOMY
RESEARCH ASSISTANT IN
INFRARED ASTRONOMY

Applications are invited for a post of Postdoctoral Research Assistant in observational infrared photometry from October 1, 1974. The appointment is for a period of one year, but extension will be considered.

The Research Assistant will continue the development of an existing infrared photometer, and its use in Tenerife and elsewhere for observations of H II regions and of extragalactic infrared sources.

Salary will be in the range £2,118 to £2,931 per annum with superannuation under F.S.S.U.

Applications, including curriculum vitae and the names of two referees, should be sent by August 24, 1974 to Dr M. J. Smyth, Department of Astronomy, Royal Observatory, Edinburgh EH9 3HJ from whom further information about the post can be obtained. Please quote reference number 5041. (591)

LINCOLN UNIVERSITY
COLLEGE OF AGRICULTURE
New Zealand

CHAIR IN AGRICULTURAL
MICROBIOLOGY

The Council of Lincoln College, a University College of Agriculture located in Canterbury, New Zealand, invites applications for appointment to the Chair in the Agricultural Microbiology at this University College.

The successful applicant will be Head of the Department of Microbiology, which is responsible for a major teaching programme from Diploma to Post Graduate level, and which has active research and advisory interests. The present establishment includes 1 Reader, 2 Senior Lecturers, 1 Lecturer, 1 Demonstrator and 3 Technicians.

Applicants should hold an advanced university degree in an appropriate field and it would be expected that they would have had experience in teaching and/or research.

The successful applicant will be appointed to the position within the existing range of professorial salaries, the commencing salary being in accordance with qualifications and experience within the range of \$NZ15,111 to \$NZ19,233 per annum.

Expenses of appointment reimbursed up to specified limits. The appointee will be eligible to join the New Zealand Government Superannuation fund, or if eligible, he may elect to continue for a limited period existing F.S.S.U. policies.

Apply in writing for Conditions of Appointment obtainable from the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, Lincoln College Canterbury, New Zealand.

Applications close on **October 15, 1974.** (582)

THE UNIVERSITY COLLEGE
OF WALES
ABERYSTWYTH

DEPARTMENT OF BOTANY AND
MICROBIOLOGY

RESEARCH ASSISTANTS

required to work on growth and development in grasses and clovers. Applications are invited from graduates in Botany, Agriculture or Biology. Successful applicants will have the opportunity to study for a higher degree.

Application forms and particulars obtainable from the Registrar to whom application should be sent by August 15. (578)

MONASH UNIVERSITY
Melbourne, Australia
DEPARTMENT OF PHYSIOLOGY
 (including Pharmacology)

SENIOR LECTURER OR LECTURER

The Department conducts courses for B.Sc., B.Sc. (Hons) and M.B., B.S. degrees and accepts graduate students for M.Sc. and Ph.D. degrees. Research interests include: brain ultra structure, neurophysiology, biophysics and pharmacology of central and peripheral synapses, muscle biophysics, circulatory physiology and pharmacology, renal and endocrine physiology.

A medically qualified candidate who can take responsibility for the organisation and teaching of a whole unit in one of the courses offered by the department is sought for 1975.

Salary scale (currently under review): Senior Lecturer (medically qualified) \$A15,143 to \$A17,224 per annum, Senior Lecturer \$A12,642 to \$A14,724 per annum, Lecturer (medically qualified) \$A11,502 to \$A14,852, Lecturer \$A9,002 to \$A12,352 per annum with superannuation based on an endowment assurance scheme, the employee and employer contributing 5% and 10% respectively.

Benefits: Travelling expenses for appointee and family; removal allowance; repatriation after three years' appointment if desired; temporary housing for an initial period. Study leave entitlement accumulates at the rate of one month's leave for each six months' service up to six years with provision for financial assistance.

Further general information and details of application procedures are available from the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria, Australia 3168, or the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. Enquiries about the Department to the Chairman, Professor R. Porter, in the University.

Closing date: **August 30, 1974.**

The University reserves the right to make no appointment or to appoint by invitation. (581)

JUNIOR TECHNICAL OFFICER

required for Chromosome Laboratory in Department of Cytogenetics and Immunology, Royal Marsden Hospital and Institute of Cancer Research. Previous experience of human cytogenetics essential. Work in progress includes studies of chronic and acute myeloproliferative disorders and the effects of treatment on chromosome breakage.

Salary according to qualifications and experience in scale £1,300 to £2,200 plus Stage III and threshold awards. Applications in duplicate to the Secretary, Institute of Cancer Research, 34 Sumner Place, SW7 3NU quoting ref. 301/B/528 (577)

UNIVERSITY OF BIRMINGHAM
SUB DEPARTMENT OF ETHOLOGY
RESEARCH ASSOCIATE
(Readvertisement)

Applications are invited from suitably qualified graduates to carry out research on the source and nature of olfactory signals in mice.

This work will be undertaken in close co-operation with a chemist and is intended to cover a three year period. Starting salary: £1,758 plus F.S.S.U.

Applications by September 10 to Dr J. H. Mackintosh, Sub-Department of Ethology, The Medical School, University of Birmingham B15 2TJ, from whom further details may be obtained. (590)

University of New South Wales
WOLLONGONG UNIVERSITY
COLLEGE
to become the

UNIVERSITY OF WOLLONGONG
1st January, 1975

LECTURER IN BIOLOGY (2 positions)

The appointees will be expected to help in the development of a course in biological energetics. One lecturer will be responsible for an instructional unit in biophysics with emphasis on cellular energy relations. The other lecturer will be responsible for an instructional unit in the physiology of multicellular organism, again with emphasis on their energy relations.

Further information may be obtained from Dr A. D. Brown, School of Microbiology, University of New South Wales, P.O. Box 1, Kensington, N.S.W. 2033, Australia.

Commencing salary for both posts according to qualifications and experience within the range \$A9,002 to \$A12,352 per annum.

Conditions of appointment and application forms available from Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

Applications close September 2, 1974. (585)

POSTDOCTORAL RESEARCH ASSOCIATE to study the molecular mechanism of hormonal activation of adenyl cyclase using both membrane and whole cell systems. Experience in molecular pharmacology, membrane biology or cellular physiology required. Applications with full curriculum vitae and names of two referees to:

Dr R. M. Epand
Department of Biochemistry
Faculty of Medicine
McMaster University
Hamilton, Ontario
Canada.

(596)

THE UNIVERSITY OF MANCHESTER

STATE REGISTERED TECHNICIAN to join team concerned with chromosome and immunogenetic research in the fields of birth defects and leukaemia. Experience in cytogenetics or immunological techniques an advantage.

Salary will be on the Whitley Council Scale for Medical Laboratory Technicians in the National Health Service.

Applications should be sent to Dr R. Harris, Department of Medical Genetics, St Mary's Hospital, Manchester M13 0JH, together with the names of two referees. (592)

Technical Field

Officer

We require a Technical Field Officer, preferably aged between 20 - 25 years, (Male or Female), who has recently graduated with a science degree. His/Her main responsibilities will be to assist in the design, running and evaluation of field trials on current animal health products and the development of new products. There will be some involvement in the area of technical sales support.

This post offers a chance to obtain experience in commercial field research and development within a large international organisation.

The successful candidate will be provided with a company car, there is a non-contributory pension scheme in operation, together with assisted B.U.P. membership and other fringe benefits.

Please apply for an application form to:-

Mr K. G. Usher,
Head of Administration,
Elanco Products Ltd.,
Broadway House,
The Broadway,
Wimbledon,
London SW19 1RR.
Telephone No: 01-542 6600.
(594)

UNIVERSITY OF SIERRA LEONE FOURAH BAY COLLEGE

Applications are invited for posts of (i) **LECTURER IN INORGANIC CHEMISTRY** and (ii) **LECTURER IN PHYSICAL CHEMISTRY**, tenable as soon as possible. For post (i), appointee should be able to give courses to general and honours degree levels in three or more of the following: Th chemistry of non-transition and transition elements; Electron Deficient Compounds; Ionic Solids; Inorganic Stereo-chemistry and Bonding; Analytical Techniques in Inorganic Chemistry. For post (ii), appointee should be able to give courses to general and honours degree levels in three or more of the following: Thermodynamics; Wave Mechanics and Quantum Chemistry; X-ray Crystallography, Molecular symmetry; Chemical Spectroscopy.

Salary scale (under review): Le2,400 to Le4,740 p.a. (£1 sterling=Le2). The British Expatriates Supplementation Scheme is unlikely to be applied to these appointments. F.S.S.U. Family passages; various allowances; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than September 4, 1974 to the Secretary, University of Sierra Leone, Private Mail Bag, Freetown, Sierra Leone. Applicants resident in UK should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (599)

British Museum (Natural History) Sub-department of Anthropology

Primatologist

■ Undertake research on fossil and Recent primates ■ Curate fossil primate collections ■ Answer enquiries on fossil and Recent primates.

□ 1st/2nd hon's degree in appropriate subject □ At least 2 years' postgraduate experience in fossil primates essential □ Interest in Recent primates desirable □ Age normally under 32 □ Appointment as Senior Scientific Officer (around £3500 - over £4750) or Higher Scientific Officer (around £2800 - £3700) according to age and experience □ Ref: SB/24/DK.

Application forms (for return by 16 August 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

**Science
group
CIVIL SERVICE**

(586)

KENNEDY INSTITUTE

Division of Experimental Pathology

CHIEF TECHNICIAN

Salary range £3000 to £4400 p.a. inclusive.

A Chief Technician is required to organise and administer the technical services of this active research group concerned with the structure and function of lymphoid tissues combining morphological and biochemical studies with particular reference to nucleic acids. Appropriate qualifications for the seniority of this post would be required. It is hoped that the successful applicant will become involved in the research activities of the group.

Experience in any of the relevant techniques which include histology, cytochemistry, autoradiography, immunology and tissue culture would be a considerable advantage.

Written applications naming two referees to the Laboratory Superintendent, The Kennedy Institute, Bute Gardens, London W6 7DW. Tel: 01-748 9966. (597)

UNIVERSITY OF RIYADH MEDICAL SCHOOL SAUDI ARABIA

(In association with the
University of London)

Applications are invited from male honours graduates for the following post at the University of Riyadh Medical School. The vacancy which is for the premedical years, has arisen as a result of the rapid expansion of the School:

DEMONSTRATOR IN PHYSICS

Applicants should have a higher degree and teaching experience.

The University of Riyadh is an independent University established in 1957. In 1968 the University established a Medical School in association with the University of London. The request by the University of Riyadh for assistance in this project is covered by a sponsorship agreement. The University of London advises on the curriculum, the form and conduct of examinations, the physical facilities for teaching, the appointment of academic staff and other matters. From the outset it has been anticipated that this assistance would continue over a period of at least 10 years possibly extending to 15 years. All teaching of medical undergraduates is in the English language.

Salary Scale: Demonstrators: Salary and housing allowance will be negotiable in accordance with qualifications and experience. Note: £1 sterling = Saudi Riyals 8.5.

Appointments are for 1 year or longer; renewable. Secondments would be considered.

Detailed applications (3 copies) including a curriculum vitae and naming three referees should be sent not later than August 16, 1974 to the Inter-University Council for Higher Education Overseas, 90-91 Tottenham Court Road, London W1P 0DT from whom further particulars are available. (600)

ANGLIAN WATER AUTHORITY GREAT OUSE RIVER DIVISION

Appointment of
LABORATORY ASSISTANT (Biology)

Applications are invited for the above appointment, preferably from persons with a degree or H.N.C. in a biological science, based in the Division's modern laboratory in Cambridge. Knowledge or experience of biological water quality survey techniques, especially on a botanical basis would be advantageous.

The salary will be within the A.P.2 grade (£1,644 to £1,926 p.a., under review, plus threshold payments) and the appointment is subject to the N.J.C. conditions of service. Removal expenses and lodging or travelling allowances may be payable.

Application forms can be obtained from the Divisional Scientist, Great Ouse House, Clarendon Road, Cambridge CB2 2BL, telephone: Cambridge 61561, to whom completed forms should be returned by August 16, 1974.

Applicants from within the Anglian Water Authority and the Water Industry will be given preference for this appointment in the first instance. (593)

THE FACULTY OF MEDICINE DIVISION OF BASIC SCIENCES MEMORIAL UNIVERSITY OF NEWFOUNDLAND

invites applications for two positions at Assistant or Associate Professor level in Biophysics/General Physiology. Preference will be given to those individuals whose research interests are in the area of biological membranes. Teaching responsibilities are biophysics or cell structure and function. Send curriculum vitae and names of three referees to Biophysics Selection Committee, c/o Associate Dean (Basic Sciences), Faculty of Medicine. (601)

ENTOMOLOGISTS

Applications are invited from qualified entomologists, for a two year appointment from October 1, 1974 as a Higher Scientific Officer or Senior Scientific Officer. Candidates should have a first or upper second class honours degree, or equivalent, and preferably postgraduate experience in the field of plant virology.

The successful applicant will be required to continue with studies which have been initiated on the incidence of vectors of grass and cereal viruses, the epidemiology and sources of resistance to insect pests. Experience with Aphididae would be advantageous.

Starting salary according to qualifications and experience in scale H.S.O. £2,461 to £3,371 or S.S.O. £3,157 to £4,441.

At least two years postgraduate experience is required for appointment as H.S.O. and four years for S.S.O.

The post is pensionable and a new superannuation scheme is being devised.

Applications by letter, together with the names of two referees, should be sent to The Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Nr Aberystwyth, Dyfed SY23 3EB not later than August 31, 1974. (595)

UNIVERSITY COLLEGE DUBLIN RESEARCH POSTS IN INVERTEBRATE ECOLOGY

A Postdoctoral Fellow or Research Assistant or Postgraduate Student is required for a 3-year project sponsored by the National Science Council on the organisation and dynamics of grassland invertebrate communities. Applicants should hold an initial honours degree in Agriculture or Zoology and preferably have research experience in quantitative ecology. Applicants graduating this autumn will be considered.

Dr J. P. Curry,
Department of Agricultural Biology,
Faculty of Agriculture,
University College,
Glasnevin,
Dublin 9.

(602)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF ZOOLOGY

A technician is required for work involving the routine maintenance of a cell culture laboratory. Experience of tissue culture work and sterile techniques would be an advantage but is not essential. Minimum qualification required is H.N.C. or equivalent. The post, which is supported on outside funds, is in the University Technical Assistant grade £1,599 to £2,022 plus threshold additions (presently under review). Application form available from Secretary, University of Cambridge, Department of Zoology, Downing Street, Cambridge CB2 3EJ. (598)

UNIVERSITY COLLEGE DUBLIN APPOINTMENT IN AGRICULTURAL BIOLOGY

Applications are invited for a teaching post in the Department of Agricultural Biology. Candidates should be honours graduates in Agricultural Science or Botany with postgraduate experience in Plant Physiology and/or Forest Botany.

The current salary scale is: Assistant Lecturer, £2,420 by £129 to £3,323.

Entry point on the relevant scale will be in accordance with qualifications and experience.

A non-contributory pension scheme and family allowances are additional to salary. An alternative contributory F.S.S.U. type pension scheme is also available.

Prior to application, further information (including application procedure) should be obtained from:

Mr J. P. MacHale,
Secretary and Bursar,
University College,
Belfield,
Dublin 4.
Telephone 693244 Extn. 431.

Latest date for receipt of completed applications is Friday, August 23, 1974. (603)

UNIVERSITY OF KEELE RESEARCH FELLOWSHIP IN BIOCHEMISTRY

Applications are invited for post of Research Fellow in Biochemistry Research Unit. The post is made possible by a grant from the Cancer Research Campaign. The appointee will join a team investigating the pharmacology of pinocytosis, and experience of cell culture would be an advantage. Salary on scale £2,118 x 129 x 165, with F.S.S.U. privileges.

Enquiries and applications to Professor J. B. Lloyd, Biochemistry Research Unit, Keele University, Staffordshire, ST5 5BG, to whom applications should be sent by August 31, 1974. (465)

UNIVERSITY OF OXFORD NUFFIELD LABORATORY OF OPHTHALMOLOGY RESEARCH STUDENTSHIP

Applications are invited from graduates in Biochemistry or Chemistry for a studentship to investigate the covalently-bound hexose of corneal collagen, commencing October 1, 1974 for 3 years.

Applications, naming two referees, should be sent to Dr J. J. Harding, Nuffield Laboratory of Ophthalmology, Walton Street, Oxford, OX2 6AW, as soon as possible. (548)

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF CHEMISTRY

Applications are invited for an S.R.C. (C.A.S.E.) STUDENTSHIP for a project involving the synthesis of a novel group of heterocyclic compounds. These are designed to possess controlled chemical reactivity and potential herbicidal character. The work will be carried out in conjunction with I.C.I. Plant Protection Limited and part of the programme will be performed at their Jealott's Hill Research Station. Applicants should have (or expect to obtain this summer) a good Honours degree or G.R.I.C. in chemistry and the successful candidate will be expected to register for a Ph.D. Applications including a curriculum vitae and names and addresses of two referees to: Dr. G. M. Blackburn, Department of Chemistry, The University, Sheffield S3 7HF (from whom further information is available). Quote Ref. R.117/G. (543)

QUEEN MARY COLLEGE University of London DEPARTMENT OF CHEMISTRY

Applications are invited for the following posts in a group working with Professor R. Bonnett on aspects of haemoglobin chemistry. Applicants should be well grounded in chemistry, but an additional interest in biochemistry would be an advantage. Starting date: October 1, 1974, or by arrangement.

Postdoctoral Fellowship in Organic Chemistry, tenable for one year in first instance, but extendable to two years. Initial salary £2,118 per annum plus £213 London Allowance.

Research Studentship, tenable for two years, leading to submission for the M.Phil. degree in Organic Chemistry.

Applications in writing (giving qualifications, previous scientific experience and names and addresses of two referees) to the Registrar, Queen Mary College, Mile End Road, London E1 4NS. (546)

UNIVERSITY OF EAST ANGLIA SCHOOL OF CHEMICAL SCIENCES SENIOR RESEARCH ASSOCIATE

required to co-ordinate and develop work on computer applications to Nuclear Magnetic Spectroscopy. The post is held in conjunction with the Science Research Council Atlas Computer Laboratory at Didcot, but the work will normally be carried out at the University of East Anglia. Contact with N.M.R. spectroscopists in other British universities, is involved. The period of appointment is two years and should start for preference on October 1, 1974.

Experience on the part of the candidate in either theoretical chemistry or N.M.R. spectroscopy or computing is desirable. The position may attract a chemist or physicist who wishes to gain full-time experience in computing. The salary will be in the range £2,118 to £2,580 per annum, the initial point depending on the qualifications of the successful candidate, plus F.S.S.U. benefits.

Applications should be sent to Dr. R. K. Harris, School of Chemical Sciences, University of East Anglia, Norwich NOR 88C, as soon as possible. The names and addresses of two referees are requested. (549)

FELLOWSHIPS AND STUDENTSHIPS

BRUNEL UNIVERSITY

(Department of Polymer Science
and Technology)

Applications are invited for the Cementation Chemicals Research Studentship from graduating and recently graduated chemists or material scientists.

Work will be in the field of solid polymer characterisation but aimed at products of civil engineering end use.

This studentship is unique in that very close liaison will be encouraged between the student/University and the industrial sponsor.

This studentship is unique in that very close liaison of M. Phil. The salary of £900 p.a. will be paid. In addition fees and reasonable expenses will be met.

Candidates—Male or Female should apply to:—

Mr. G. R. Southern,

BRUNEL UNIVERSITY

Department of Polymer Science,
Kingston Lane,
Hillingdon, Uxbridge.

(535)

INSTITUTE OF UROLOGY (UNIVERSITY OF LONDON)

in association with St. Peter's Hospitals

Applications are invited for a Research Fellow (with medical and/or scientific qualifications), in the grade of Lecturer (Senior Registrar status), for an investigation into the ultrastructure of the kidney and urinary tract epithelium. The successful applicant will be attached to the Electronmicroscopy Unit in the Department of Pathology, St. Paul's Hospital. Appointment for one year in the first instance, subject to renewal for a further period of two years. Applications to the Pathologist (N), St. Paul's Hospital, Endell Street, London, W.C.2. (390)

INSTITUTE OF UROLOGY (UNIVERSITY OF LONDON)

in association with St. Peter's Hospitals

Applications are invited for a Research Fellow (with medical and/or scientific qualifications), in the grade of Lecturer (Senior Registrar status), for an investigation into the ultrastructure of the kidney and urinary tract epithelium. The successful applicant will be attached to the Electronmicroscopy Unit in the Department of Pathology, St. Paul's Hospital. Appointment for one year in the first instance, subject to renewal for a further period of two years. Applications to the Pathologist (L), St. Paul's Hospital, Endell Street, London, W.C.2. (391)

UNIVERSITY COLLEGE LONDON RESEARCH STUDENTSHIP

Applications are invited from graduates (Class I or 2i) in Biochemistry or Zoology with biochemical interests to participate in a programme of research on haemoglobin and other blood proteins of lower Primates. Apply to Professor N. A. Barnicot, Dept of Anthropology, University College London, Gower Street, London WC1E 6BT. (545)

UNIVERSITY OF WESTERN AUSTRALIA Perth FORESTS DEPARTMENT POSTGRADUATE RESEARCH FELLOWSHIP IN BOTANY

Applications for the above-mentioned appointment are invited from graduates with a first-class or upper division second-class honours degree in Botany, and Forestry or Agriculture graduates whose courses of study have extended over at least four years and who have had appropriate research experience. The Fellowship, financed by the Forests Department of Western Australia, will be tenable for one year initially with prospects of renewal for up to two further years. The value of the Fellowship is \$A3,150 per annum. The Fellow will be required to undertake research in a field covering mycological, physiological or ecological aspects of tree growth in relation to multiple use forestry, or such other fields as may be prescribed.

Further information may be obtained from the Head of the Department, Professor J. S. Pate, in the University.

Applications in triplicate stating personal particulars, academic record, research experience, work proposed, etc., should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by December 31, 1974. Candidates should request two academic referees to write immediately to the Staffing Officer.

Conditions of Appointment obtainable from the Association of Commonwealth Universities, (Appts) 36 Gordon Square, London WC1H 0PF. (544)

UNIVERSITY OF EDINBURGH DEWAR FELLOWSHIP FUND Applications are invited for a

SENIOR RESEARCH FELLOWSHIP

tenable in the Department of Physics for a period of 2 years from October 1, 1974 (or as soon as possible thereafter). Applicants should hold a Ph.D. or equivalent qualification.

Salary will not be less than £2,118 per annum with F.S.S.U. benefits.

The Selection Committee will retain discretion, if a candidate of sufficient distinction is not available, to recommend the award of a

JUNIOR RESEARCH FELLOWSHIP

with salary in the range £1,400 to £1,600 with F.S.S.U. benefits.

Preference will be given to candidates whose intended fields of research lie in domains in which the subjects of physics and chemistry overlap.

Applications, naming two referees in each case, should be lodged with Professor W. Cochran, F.R.S., Physics Department, James Clerk Maxwell Building, Mayfield Road, Edinburgh EH9 3JX, not later than September 6, 1974. Please quote reference number 7009. (547)

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY S.R.C. RESEARCH STUDENTSHIPS

Applications are invited for two research studentships within the department. Research will involve study of the metabolism of steroidal and non-steroidal drugs, in which the department already has an active interest.

The proposed programme of study would give the student instruction and experience in a wide range of chemical, analytical and biological techniques which are currently being employed in both industry and academic departments for studies in biochemical pharmacology and drug safety evaluation. Applicants are expected to have a first or upper second class degree in a relevant subject.

Applications, including a brief curriculum vitae and the names of two referees should be sent as soon as possible to:-

Mrs M. L. Whitley (Ref: JC/AS)
Department of Biochemistry,
University of Surrey,
Guildford,
Surrey. (496)

European Molecular Biology Organization (EMBO) Short- and long-term fellowships in molecular biology

The European Molecular Biology Organisation intends to award to scientists working in laboratories within the European area both short-term (from a few days to several weeks) and longer-term fellowships for collaborative research or advanced training in molecular biology.

The Short-term Fellowships are to support visits to other laboratories for the purpose of carrying out experiments with special techniques or of other forms of scientific collaboration or advanced training, and especially to support developments arising at short notice.

The Long-term Fellowships will usually be for a period of one year, but applications for renewal will be considered. They will be awarded upon individual application, at the "junior" level to promising young research workers who may then spend prolonged periods in other laboratories working under the guidance of leaders in the field of molecular biology. At the "senior" level, they may be awarded to enable established research workers to gain experience in new approaches and new problems. Upon application by European Institutions fellowships at the "senior" level may also be awarded to specialists who can assist in the initiation and development of research programmes in the sponsoring Institution. Such "sponsored" awards may be made to established workers at all stages of their career beyond the postdoctoral stage.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organisation, 6900 Heidelberg 1, Postfach 1022.40, Germany. (521)

IMPERIAL COLLEGE

Applications invited for Research Studentship leading to Ph.D., sponsored by the Analytical Chemistry Trust of the Society for Analytical Chemistry, for investigation of the application of the Opto-Acoustic Effect to Trace Analysis. Candidates should possess a good honours degree from a British University or an equivalent qualification acceptable to the trustees. Further information from, and applications to: Dr G. F. Kirkbright, Department of Chemistry, Imperial College, London, SW7 2AY. (508)

QUEEN'S UNIVERSITY, BELFAST

Studentship in Biochemistry

Applications are invited for a research studentship, three years, leading to a Ph.D. degree. The research topic is the significance of immunoreactive secretin in health and disease, which is part of a collaborative research programme of the Departments of Biochemistry and Medicine. The work will involve radioimmunoassays and immuno-affinity chromatography.

Applications including names of two academic referees should be sent to Dr R. F. Murphy, Department of Biochemistry, Medical Biology Centre, Queen's University, Belfast, BT9 7BL. (540)

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF CHEMISTRY

POSTDOCTORAL FELLOWSHIP

Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP for studies on models of the iron-binding site of transferrin, tenable from September 1, 1974. The work will involve the isolation and study of iron compounds of multidentate ligands—especially by X-ray crystallographic methods. Candidates should hold a Ph.D. in Inorganic Chemistry and experience in both transition-metal chemistry and X-ray crystallography is desirable. Tenure one year but may be renewed for a second year. Salary up to £2,058 or £2,247 from October 1. Applications, with the names and addresses of two referees, to Dr N. A. Bailey or Dr E. D. McKenzie, Chemistry Department, The University, Sheffield S3 7HF. Reference R 121/G. (552)

RHODES UNIVERSITY GRAHAMSTOWN, 6140 SOUTH AFRICA

HUGH KELLY FELLOWSHIP

The Rhodes University Council announces the establishment of the Hugh Kelly Fellowships. The Fellowships are for senior scientists wishing to undertake or continue their research in any of the departments within the Faculty of Science; the first of these Fellowships will become available in 1975. The Faculty comprises the Departments of:-

Botany, Chemistry, Geography, Geology, Mathematical Statistics, Mathematics (Applied, including Computer Science), Mathematics (pure), Microbiology, Pharmaceutical Sciences, Physics, Psychology, Zoology and Entomology.

Closely associated with a number of these departments are the Leather Industries Research Institute, the Institute for Freshwater Studies and the J.L.B. Smith Institute of Ichthyology.

The Fellowship in 1975 is available for a period of six months, which period shall include two academic terms of the University. The emoluments attaching to the Fellowship include an award of R4 000 (R1—approximately 62 n.p. sterling) and a tourist class return air fare from the Fellow's place of residence.

The Fellow will be required to present the Hugh Kelly Lecture on a subject of his choice during the tenure of the award.

Forms of application and further particulars may be obtained from the Registrar, to whom completed applications should be submitted by October 31, 1974. (515)

LA TROBE UNIVERSITY MELBOURNE, AUSTRALIA RESEARCH FELLOW IN GENETICS AND HUMAN VARIATION

(one or two positions)

Applicants will be appointed for one or two years, with possible extensions up to a total tenure of three years. They will be expected to work in one of the areas of interest of the Department which include behavioural, cellular, ecological, human, microbial, population and quantitative genetics and cytogenetics. Enquiries may be directed to Professor P. A. Parsons, Chairman of the Department, in the University.

Salary: \$A7,545 to 2 by \$A292 to 3 by \$A291 to 4 by \$A479 to 5 by \$A478 to \$A12,352.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, La Trobe University, Bundoora, Victoria, Australia 3083.

Applications close on September 13, 1974. (529)

UNIVERSITY OF LEICESTER

Applications are invited for a CASE STUDENT-SHIP. The Successful applicant will work with professor M. C. R. Symons on a research project entitled "Quantitative study of Autoxidation Reaction with the aid of E.S.R. and kinetic techniques". The research will be conducted in cooperation with Dr N. Uri, and the student will spend a proportion of his/her time at the research laboratories at Waltham Abbey during the 3-year Ph.D. training.

Applications should be made to professor M. C. R. Symons, Department of Chemistry, University of Leicester, Leicester LE1 7RH, from whom further details may be obtained. (525)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL FELLOWSHIP

Applications are invited from Physicists and Chemists for a postdoctoral fellowship to study some of the unusual properties of liquid crystals. Attention will be concentrated on the behaviour of a liquid crystal when it is subject to a magnetic field and a viscous torque produced by spinning the sample. The response of the system to these two perturbations will be monitored with the aid of electron resonance spectroscopy. Previous experience in this branch of spectroscopy or of liquid crystals would be an advantage.

The fellowship is available for a period of one year with a Salary £2,247 per annum, plus F.S.S.U. benefits.

Applications, including a curriculum vitae, list of publications and the names of two referees should be sent, as soon as possible, to: Dr G. R. Luckhurst, Department of Chemistry, The University, Southampton SO9 5NH. (541)

A small number of FELLOWSHIPS for one, two or three months are available in 1975. The salary will amount to about 4,500£ a month. Travel costs are at visitors own expense. Applications with list of publications should be sent before December 1, 1974 to:

Monsieur le Directeur de l'Observatoire de Nice
Le Mont Gros
06300 - NICE
FRANCE. (584)

THE UNIVERSITY OF
ASTON IN BIRMINGHAM
DEPARTMENT OF BIOLOGICAL SCIENCES
RESEARCH FELLOW
IN FISH BIOLOGY

Applications are invited for a Research Fellow to work in a small research team led by Mr H. A. Hawkes, studying the effects of a sewage effluent on the survival, growth and tissue contamination by metals of fish populations in simulated streams. Experience in fishery biology—involving population studies and/or fish toxicology—involving histochemical techniques is required. The appointment which will date from October 1, 1974 will be for a period of three years.

Commencing salary will be within the range £2,118 to £2,412 per annum on a scale rising to £3,636 per annum.

Requests for further details and application forms (which should be returned not later than August 26.) should be sent, preferably on a postcard, quoting Ref. No. 988/... to the Staff Officer, the University of Aston in Birmingham, B4 7ET. (556)

UNIVERSITY COLLEGE DUBLIN
FACULTY OF AGRICULTURE
POSTDOCTORAL RESEARCH
FELLOW

Applications are invited for a postdoctoral research fellowship to collaborate on a study of factors affecting intake and metabolism of silage by ruminants on a three year project sponsored by the National Science Council.

Starting salary at £2,100 p.a.

Applicants should have a degree in Agriculture or Biochemistry or Microbiology, followed by appropriate research experience.

Enquiries and applications should be sent to:

Department of Agriculture Chemistry,
Dr J. L'Estrange,
University College,
Glasnevin,
Dublin 9. (604)

UNIVERSITY COLLEGE DUBLIN
DEPARTMENTS OF ZOOLOGY AND BOTANY
RESEARCH FELLOWSHIPS IN
RIVER ECOLOGY

Two posts are offered for Research Fellows to cooperate in a "Base-line Survey of the Caragh River, Co Kerry". Candidates should have obtained a Ph.D. or be about to submit; those with an M.Sc. only will be considered if they have appropriate experience. Experience should include the following:

Fellowship I—A general knowledge of stream and river fauna with expert knowledge in at least two of the following orders (Ephemeroptera, Plecoptera, Trichoptera or Diptera-Chironomidae).

Fellowship II—A knowledge of fresh-water algae and techniques for the determination of their productivity.

A knowledge of appropriate physical and chemical techniques is desirable for both applicants.

The salary offered to a suitably qualified applicant is £1,800 to £2,250 depending on qualifications. The position is tenable for one year with a possible extension to a second year. The work will be based in Dublin and an allowance for field expenses will be paid.

It is hoped that candidates would take up the posts on October 1, 1974.

Applications should be forwarded to the undersigned, together with details of qualifications and the names of two referees before August 7, 1974.

SUBSCRIPTION—
REDUCED RATE OFFER

The publishers appreciate that the inevitable high cost of an annual subscription to **Nature** restricts many regular readers to a circulation or library copy of the journal; these readers unfortunately do not enjoy the privilege of a personal copy to read at leisure and to keep for future reference.

To help such people we are making an offer (for a limited period) of a twelve months subscription for only £15 on condition that application is made on and within the terms described on the coupon attached. We regret that for the time being this offer can only be made to people with addresses in the U.K. and that it will be withdrawn on 31st October 1974.

If this experiment is successful, we hope to be able to repeat it and extend it over a wider area.

Bringing automatic chemistry down to size

ABA-100 will provide your laboratory with a fully automatic, accurate and highly flexible clinical chemistry analyser, which combines high workload capacity with high resolution spectrophotometry, both in the ultraviolet and visible.

Speeded up to 150 samples per hour.

Automatic processing, data handling and print out.

Convenience

Automatic end points, 30°C or 37°C,* temperature conversions, increasing or decreasing absorbance measurement with the flick of a switch.

Accuracy & Precision

C.V.'s typically better than 2% in the normal range.

Temperature maintained to within $\pm 0.1^\circ\text{C}$.

Automatic reagent blank correction.

Data calculations and conversions performed by integral mini-computer.

Conversion directly into IU/l or mgm.

Automatic warning of *non-linear rate reactions*.

Economy

Saves substrate—uses as little as 250 μl .

Saves serum—uses as little as 5 μl .

Saves time—30 glucose in 10 minutes.

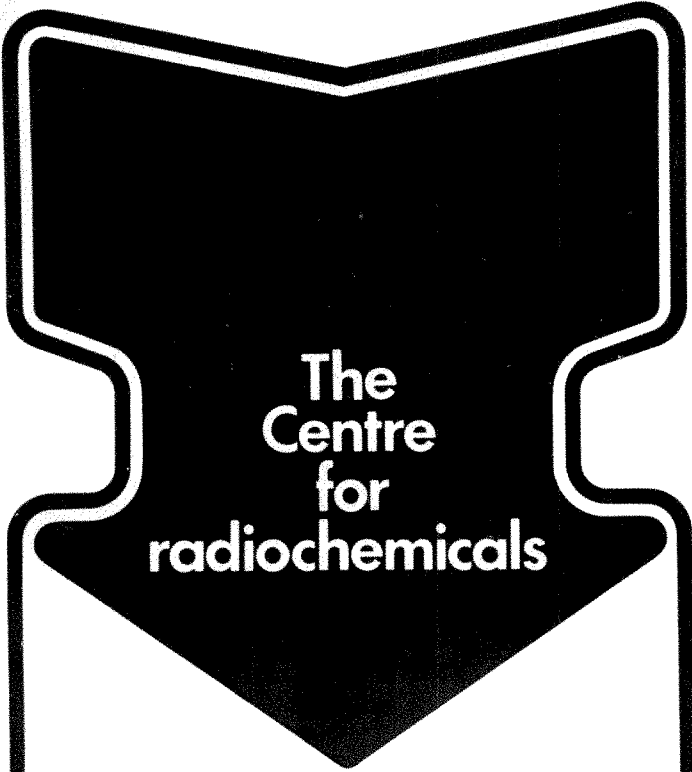

Saves space—only 4 cubic feet of bench space.

* 25°C AVAILABLE.

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is published monthly and sets out to cover all aspects of the fight for life of lakes, estuaries, seas and oceans. It includes news, comment, reviews and research reports not only on the threats of noxious substances to marine life but also on the management and productivity of the marine environment in general. It publishes accounts of new and proposed research programmes as well as the results of those in progress.

Recent research reports include:

Distribution of Caesium-137 in British Coastal Waters, D. F. Jefferies, A. Preston and A. K. Steele. **Export of Lead from Salt Marshes**, M. Banus, I. Valiela and J. M. Teal. **International Scope of Marine Pollution Damage**, D. P. Tihansky. **Effects of Red Mud on Marine Animals**, R. A. A. Blackman and K. N. Wilson. **Pollution Problem of the Golden Horn**, M. Karpuzcu.

Annual Subscription £6.00 (£7.50 USA and Canada). Prices applicable only to orders starting before 31 December 1974. Payment may be made in any currency at the current exchange rate. Cheques should be made payable to Macmillan Journals Ltd., Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

THE CHOICE OF A ROLAMIX

Laboratories throughout the world have been using the Rolamix when they require a thorough blending of specimens. The unique "double action" of rocking and rolling has been proved to be a time saving and very successful method of blending including fluids, plasma, powders and blood without frothing.

Now there is a choice of two models, the standard RM/54 with four power driven and five skid rollers or the RM/54A which has all nine rollers power driven. This facility overcomes the problems of rolling small light plastic bottles and where labels are not stuck on properly and also where the caps are larger than the bottle diameter.

Radioimmunoassay?

Searle Diagnostic
now supply from stock and by return
of post the following antisera for
radioimmunoassay, freeze-dried in vials,
containing sufficient for 200 tubes

- **Anti-testosterone-3-BSA** (sheep)
- **Anti-17 β oestradiol-6-BSA** (sheep)
- **Anti-testosterone-3-BSA** (rabbit)

These products, the first of a range, have
been developed from routine use and
research into steroids in the Searle
Scientific Services Laboratory

**Steroid Antisera
for Radioimmunoassay**

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Affinity labelling the acceptor site of the peptidyl transferase centre of the *Escherichia coli* ribosome—D. Eilat, M. Pellegrini, H. Oen, N. de Groot, Y. Lapidot and C. R. Cantor 514

Identification of a population of mouse leukocytes using wheat germ agglutinin—P. J. Robinson and I. M. Roitt 517

Adjuvant activity in delayed hypersensitivity of the peptidic part of bacterial peptidoglycans—J. Fleck, M. Mock, F. Tytgat, C. Nauciel and R. Minck 517

Statistical calculations: the one digit answer.

This is the Canon F20P, designed especially for statistical work. It has many features that will make your calculations quicker and easier to perform and among them, there is this one that might appeal to you. You enter data once and once only. Then, at the stroke of just one key you obtain: Mean, Maximum, Minimum, Range, Unbiased Variance, Standard Deviation, Standard Error, Correlation Coefficient, Linear Regression Estimates, Normal Deviate and Standard Normal Probability.

Canon calculators are sold through office equipment dealers. For complex applications, we support these dealers with our Technical Sales Support Team. They are

experienced in analysing problems and coming up with answers. Send now for either the name of your nearest Canon calculators stockist, or a visit from one of our specialists. It will be very much worth your while seeing an F20P in action.

- ☐ Please let me know my nearest Canon stockist.
- ☐ I would like a visit from one of your specialists.

The time-bomb ticks on

IN 1969 the Institute of Race Relations in London produced a massive report on race in British society, and in particular the problem of the coloured immigrant. *Colour and Citizenship* was a mine of information, not all of it very palatable. It also had some strong recommendations to make on the subjects of education and employment.

Broadly, the report recommended that the Race Relations Board "should make full use of its powers to initiate investigations". It continued, amongst other things, to say, "it is essential for a non-discriminatory employment policy that records be kept which distinguish employees by ethnic origin." This would be seen by some as discriminatory in itself, but there was felt to be no other way to determine whether minorities were afforded equal opportunities.

Five years later, the House of Commons Select Committee on Race Relations (in a report issued last week) is still loath to grant the Race Relations Board legal powers to initiate investigations, being dissatisfied with the preventive work it has done so far.

But how does all this affect the scientist; surely this is a matter with which he may have some general liberal sympathy but is it not really an affair for the industrial shop-floor?

About 2% of the population of Britain is coloured immigrant or of immigrant descent. West Indians comprise half this figure, Indians and Pakistanis another 40% of it. By 1986 the 2% will be up to 3% or maybe 4%, depending on immigration policies and fertility. It is erroneous, even now, to assume that the distribution by age of this section of the population is such that the children of coloured immigrants are not yet at an age at which others seriously consider further education, say 16 to 21. The percentage of immigrants in this age bracket is close to the percentage of the general population in the same bracket. Two percent of those eligible, in terms of age, for a university education are immigrants or of immigrant descent.

The next question is, obviously, how many are getting a university education, and it is at this stage that problems arise. Every university campus is, of course, a very multiracial affair but many of those contributing to this are temporary immigrants, in Britain for educational purposes. It is impossible to get statistics about permanent immigrants at university; these figures do not exist, indeed some university registrars expressed surprise that we should wish to know the numbers, as in order to be scrupulously fair they could not possibly ask of candidates for admission anything more probing than their place of birth.

This seems a wrong if well intentioned policy, and the sooner it is rectified in universities the better; the select committee has come to a similar conclusion in the more general fields of employment (duplicating the 1969

proposals of the Institute of Race Relations).

Those who do not learn from history are forced to relive it, and there are the clearest lessons from recent American history. American experience—with a much larger minority group population—is that passivity in matters of race relations leads to greater alienation. It was simply not good enough to bemoan the lack of suitably qualified applicants and place the blame elsewhere—in the schools, in the social system or whatever. Accordingly the whole process of acquiring staff as well as students in many American universities, and particularly those with government contracts, is a complex business of satisfying law enforcement agencies that positive steps have been made to recruit minorities. This is a tedious process in many ways, and is both irritating to the academic community and somewhat humiliating to the minorities involved. On the other hand, blunt as it is, it is the only tool available to ensure that at least those who have some aspirations towards higher education do get reached.

It would probably be wrong at present to go for measures as drastic as this in Britain if there is any hope that lesser measures can succeed, and there may be a few years left before alienation is so total amongst some immigrants that the thought of a university education is anathema. But the next few years will require some positive action—one idea widely supported is that since many immigrants only discover in their twenties that they have unrealised potential for which higher education would have been beneficial, universities should come to terms with a fairly regular intake of more mature immigrant students. Another need expressed by workers in areas of high immigrant numbers is for more people from places of higher education to visit their community, not to announce that they are lowering standards for immigrants, but to give potential students the challenge of raising their own standards.

LADY BARKER'S "LESSONS ON COOKING"

First Lessons in the Principles of Cooking. By Lady Barker (London: Macmillan and Co., 1874).

IN this little volume the authoress has proved beyond all manner of doubt how completely she is the right woman in the right place. Surely nowhere could the Committee for the National Training School for Cooking have found a lady superintendent better fitted than Lady Barker to put life and spirit into the scheme which they advocate, or one more thoroughly qualified to train and marshal the feminine bands that are now being drilled under her supervision in the South Kensington Schools of Cookery to invade and revolutionise the kitchens of the future in every part of the empire.

From *Nature*, 10, 283, August 13, 1874.

The unendangered whale

Dr Ray Gambell, of the Whale Research Unit at the British Museum (Natural History), discusses the new rules for whaling adopted by the International Whaling Commission this year and argues against previous calls for a complete moratorium.

EVER since the 1972 Stockholm conference on the human environment there has been a persistent call to impose a 10-year ban on commercial whaling. This year's annual meeting of the International Whaling Commission (IWC), held in London in June, again considered this proposed moratorium. The IWC's Scientific Committee advised that because the concept of individual species management is now operative, there is no biological requirement for a blanket ban on all catching, and indeed, catching of some species may be necessary to promote the maximum rebuilding of other depleted stocks because of interspecific competition.

The IWC, which regulates about 90% of the world's whaling, therefore adopted an amended moratorium proposal which sets out the criteria by which the various whale stocks will be harvested in future. Briefly, these divide whale stocks into three categories; 'protection stocks', which will not be hunted at all; 'sustained management stocks', which can be caught at carefully controlled levels; and 'initial management stocks', which are very abundant and can also be taken in suitably regulated numbers to prevent any risk of over-exploitation.

By adopting this regime for future commercial whaling activity, the IWC has effectively placed the regulation of whaling in the hands of its Scientific Committee. This committee is charged with the responsibility of allocating the various whale stocks into the three categories defined above, and then deciding the level of catch which each can sustain if it is available for exploitation. The original Convention for the Regulation of Whaling signed in 1946 was formulated to provide for the conservation, development and optimum utilisation of the whaling resources. This was to be based on scientific findings, but could also take into account the interests of the consumers and the whaling industry. In the past the

economic arguments of the latter two groups often outweighed the advice given by the scientists, with the consequent decline of some of the major whale stocks. Now the emphasis has swung very much towards the scientific side. It remains to be seen just how well the scientists can resist the political and economic pressures which up till now have been exerted mainly in the full commission meeting rather than in the Scientific Committee.

The present scheme for the management of the whale resources can be seen as part of the general development of the policy adopted by the IWC in recent years. This is based on the concept of sustainable yield. In a stable, unexploited population the number of new recruits exactly balances the deaths due to natural mortality. When the population size is reduced by whaling, the recruitment rate increases through a lowering in the age at which the animals become sexually mature, and also by an increase in the pregnancy rate. The natural mortality rate also falls as whales are caught before they have a chance to die naturally.

The exact forms of the relationships between the changes in recruitment rate and natural mortality rate with decreasing population size are not known for

certain in the whales, although there is some evidence from blue, fin and sei whales that the recruitment rate increases linearly. In Fig. 1a such a linear form for the variation in a theoretical net recruitment rate with population size is shown. This represents the gross recruitment by reproduction less the natural mortality. Multiplying every population size by the appropriate net recruitment rate gives a number, plotted in Fig. 1b, which is the surplus of recruitment over natural deaths. This surplus is a yield which can be harvested indefinitely without changing the overall population size. As can be seen from Fig. 1b, the yield is small in populations which have been much depleted in size. It is also small in those populations which have been but little reduced. The yield reaches a peak, the maximum sustainable yield (MSY), at some intermediate population size which is generally around half the original population number. Catching the sustainable yield will hold a population at its present level. Catching less than the sustainable yield will mean an addition to the total population size, which will therefore increase in numbers. For a population which is smaller than the level giving the MSY, this will allow some rebuilding towards that level; a population above that level will increase still further. Conversely, catching more than the sustainable yield will deplete the population, and for a population already below the MSY level will make it still less productive.

It is relevant now to consider where the various whale populations stand in relation to their MSY positions. In both major whaling areas, the Southern Hemisphere and the North Pacific, the same species are in very similar states. Blue, humpback and right whales are very seriously depleted and far to the left in the yield diagram (Fig. 1b). This is why they are totally protected from catching by the IWC. Grey whales in the North Pacific are also protected, although they have recovered from a very low level and now seem to be stabilised near their former original number.

Sei whales are close their MSY levels in both regions, although there are some variations between the component stocks in each case. Male sperm whales are also close to their MSY levels, but the females are relatively unexploited and far to the right of the yield diagram. Antarctic minke whales are also very

Fig. 1 *a*, A theoretical relationship between the net recruitment rate and a whale population size. *b*, Sustainable yield at each whale population size derived from the theoretical recruitment relationship.

The end of the line.

Copyright: National Institute of Oceanography.

abundant, as they have only been caught in large numbers in the past two seasons.

Fin whales, although a major component of the whaling industry's economy, are only at a third or a half of their MSY levels, and so need to rebuild in both regions.

Since 1965 the IWC has had the stated intent of setting the catch limits below the sustainable yields as calculated by continuing assessments. At that time the catch limits for the Antarctic baleen whale were set in terms of Blue Whale Units (BWU). One BWU equalled 1 blue whale, 2 fin whales, $2\frac{1}{2}$ humpbacks or 6 sei whales. These values were based on the relative oil yields of the different species, but the system was unfortunate because it took no account of the fact that each species may need a different degree of protection. The same criticism can also be levelled at the idea of a total moratorium on whaling, for not all whale stocks require such protection.

Catches of whales in the North Pacific have always been limited on a species basis, and from 1972 the Antarctic catch limits have also been set species by species. An even finer degree of control would be achieved by regulating the breeding stocks independently, but these cannot yet be fully identified. As a move in this direction, though, the IWC has now subdivided the Antarctic into three areas, and imposed maximum catches for each species in each of these areas.

Sperm whales, the largest of the toothed whales, did not come into the BWU system. In 1972 the Scientific Committee recommended that the catches of this species should be limited by each sex separately. This is practicable because the male sperm whales grow considerably larger than the females. The females had been protected from much catching by a minimum size limit. The Scientific Committee therefore also recommended that this size limit should be reduced, so that more females could be caught to bring the sexes into better balance. This is reasonable with the total catch limits imposed, which include a subdivision of the Southern Hemisphere into three areas with separate limits for the sexes in each.

The overall catch limits set this year are summarised in the Table, together with the estimates of sustainable yields. It is apparent from all this evidence that

the catches will not cause any species to be in danger of becoming extinct. Even the fin whale, which is the most reduced of the major species still hunted, should be rebuilding slowly. In addition, the IWC is committed to stop the capture of all fin whales in these two regions at least by 1976, so that the populations will then increase at the maximum rate possible.

The Scientific Committee will hold a special meeting to consider the assessment and status of all whale stocks in time to advise the commission next year on these matters. In addition, it will put forward detailed plans for extensive monitoring and research on the stocks. It is hoped that the costs of these projects, running into several millions of pounds, will be met by the United Nations (UN) Environment Programme, the UN Food and Agri-

cultural Organisation and other similar agencies.

There is much research needed. Up to the present, each whale species has been considered in isolation, without regard to the other whale species or the rest of the environment. Evidence of intelligent actions is now becoming available. In addition, concepts involving the biology of whales rather than their numbers will require study before they can be incorporated into the sustainable models already employed.

At all events, the future for whales looks bright. There is no danger of any of them disappearing through overexploitation under the present controls, and there is the prospect of management being grounded on rational policies designed to provide the greatest long term benefit from this considerable natural resource of the oceans.

Overall catch limits set by the IWC and the estimated present sustainable yields of the whale populations

	Antarctic		North Pacific

♀	5,000	4,500	4,000	1,700

*Whole Southern hemisphere.

international news

Two years ago a massive research programme on cardiovascular disease was launched in the United States when Congress passed a bill inelegantly entitled the National Heart, Blood Vessel, Lung and Blood Act of 1972. Modelled on the rhetorically overburdened campaign for the conquest of cancer, the research programme has received enthusiastic endorsement by President Nixon, who has repeatedly reaffirmed the administration's commitment to find ways of reducing the death toll from heart disease—"the nation's number one killer". But an expert committee, which is supposed to keep an eye on this frenzied research programme has charged that the effort so far has been grossly underfunded and badly misdirected. In short, the Administration's commitment has been long on rhetoric but short on dollars.

The criticisms were made in a report to Congress by the National Heart and Lung Advisory Council which was actually written in December last year but which has spent the past seven months being reviewed by the Office of Management and Budget and the Department of Health, Education and Welfare. President Nixon finally passed the document on to Congress last week with the message that it "merits serious consideration", although it contains recommendations which are "at variance with the Administration's views".

Chief among those recommendations is that the National Heart and Lung Institute (NHLI) should be given a budget this year of \$520 million, instead of the \$309 million proposed by the Administration. The council charged that the amount of money being spent on cardiovascular research was actually

Heart research short on cash

by Colin Norman, Washington

less last year than in 1968 if inflation is taken into account, and it reported that "the resources for this accelerated attack [on heart disease] have not been forthcoming".

Such complaints have come as no surprise to the Administration, or to anybody else for that matter, since the council is composed chiefly of scientists directly or indirectly engaged in research on cardiovascular disease, and the report thus has all the appearances of special pleading by a section of the biomedical community. Although the Administration has so far made no formal public response to the council's recommendations, officials point out that the National Heart and Lung Institute (NHLI) has in fact fared relatively well. Since this year the Administration proposed a hefty increase in its budget (\$25 million) while all the other institutes at the National Institutes of Health with the exception of the National Cancer Institute either had their budgets cut or kept static.

Nevertheless, it is difficult to deny that much of the proclaimed attack on heart disease has gone off at half cock, at least when it is measured against the intentions of the 1972 Act. The Bill suggested that \$460 million should be spent by NHLI in the 1974 fiscal year—which ended on July 1 this year—and that \$520 million should be spent in the 1975 fiscal year. Only \$280 million was

spent last year, however, and the Administration has proposed a budget of \$309 million for 1975.

Aside from the question of funding, the council also takes the Administration to task for a variety of other sins, chief of which is the move early last year to abandon the policy of providing fellowships and traineeships for biomedical scientists. Although the council neglects to mention that in July last year the Secretary of Health, Education and Welfare, Caspar Weinberger, announced that the Administration would not scrap the training programmes after all, it states that the unavailability of funds for biomedical training "has reduced the research manpower and the productivity of many of the very best research groups supported by the National Heart and Lung Institute." (Last month, Congress finally approved a bill which will more than double the Administration's proposed expenditure on biomedical research training. Administration officials said last week that they are looking at ways to implement the bill, and presumably that will still the criticisms of the council.)

The council also comes up with a clutch of recommendations for endowing chairs at universities for professors engaged in cardiovascular research, for maintaining a good balance between grants and contracts, and for establishing special research and demonstration centres around the country. Another prominent suggestion is that Congress should establish minimum qualifications for members of the council itself; this is believed to be a reference to the fact that the singer Frank Sinatra was appointed to the council last year, but failed to attend any of its meetings.

A SOUTH AFRICAN gynaecologist is pioneering a technique for fallopian tube transplant operations which may offer a better answer than *in vitro* fertilisation for childless women.

For *in vitro* fertilisation to take place the egg must be caught at the precise moment of ovulation, and since ovulation can occur at any time, doctors must be on constant alert and time-consuming observations of the woman is needed. By contrast, the suggested transplant technique is much simpler and cheaper, because after a short operation nature can take its course.

According to Dr Abraham Rubin, he and his colleagues at the University

Transplant babies?

from Ian Ridpath

of the Witwatersrand Medical School in Johannesburg are hoping to start soon an experimental programme that will lead to the first operation of this kind in women.

Fallopian tubes for transplant are readily available from women who have had a hysterectomy. Substituting them for diseased tubes is a relatively simple operation that is little more than an extension of existing surgical techniques regularly used by gynaecologists. Successful fallopian tube

transplants have already been performed on sheep by Dr M. Katz at the University of Cape Town, and Dr Rubin thinks that the same technique can be extended to humans.

It would be particularly valuable where infection of the fallopian tube is common, says Dr Rubin. Unlike other forms of transplant there are no worries about rejection, since the technique is to use the tube for one cycle and then it can be removed. Rejection only becomes a problem after three to four weeks. Donors do not therefore have to be specially selected, which helps to make the operation more widely available, and Dr Rubin envisages it being performed regularly.

Geologists as professionals

from Peter J. Smith

PHYSICISTS, chemists, biologists and mathematicians in Britain have their respective professional institutes, and there are no less than 15 chartered institutions catering for the needs of the various types of engineer. British geologists, by contrast, have no professional body, although members of certain subdisciplines within the earth sciences are eligible to join appropriate existing organisations (some geophysicists, for example, are members of the Institute of Physics). So is there a case for the formation of a professional Institute of Geology? A working group sponsored by the Geological Society believes there is, and in its published report (*Report of the Working Party on Professional Recognition*, Geological Society of London; 1974) recommends that the degree of support for a professional organisation in geology be widely tested.

The Geological Society itself is a learned society, but has lately been finding it difficult to reconcile its traditional role with the need to represent British geology to the outside world. As an example of this need, the report cites the setting up in 1973 of the Council of Environmental Science and Engineering by the two councils representing, respectively, the professional science institutes and the chartered engineering institutions. Because there is no professional body of geologists affiliated to the two sponsoring councils, geologists have no formal participation in an organisation concerned with environmental problems.

Because earth science is one of the two branches of science most directly concerned with the environment, the need for a 'voice of British geology' is clearly much more than a parochial academic matter. The Geological Society working group has therefore examined in some detail the case for a professional body which "would be expected to provide representation of geological interests at different levels". But external representation is not the only, nor perhaps even the principal function of a professional institute; and it is envisaged that the proposed Institute of Geology would also operate a code of ethics and professional conduct, set professional standards for the various categories of membership, provide advice on career structures and personal security, and disseminate information on general and professional matters.

But if the idea of an Institute of Geology (by this or any other name) comes to be widely accepted, how could it be put into practice? The re-

port considers five "alternative [sic] pathways" (in addition to maintenance of the status quo) but in the end rejects four of them as unlikely to succeed. The first—the creation of a professional class of Fellowship within the Geological Society—was rejected at an early stage in the discussions because although it would strengthen the society financially and allow it to speak for professional geology nationally, it would probably lead to a dissension among the ranks of the non-professional geologists (the "second class Fellowship"). Moreover, there is some doubt as to just what professional services the society would be allowed to offer under the terms of its Charter; the lack of significant additional services recently led to the failure of a similar scheme in South Africa.

Indeed, the Charter seems to be a major stumbling block, for both it and the society's grace-and-favour apartments might also be put at risk by two other possible schemes — a more thoroughgoing conversion of the society into a professional-cum-learned society (a solution adopted by the physicists) or the creation of a new body under the society's direct sponsorship. This then leaves just two other possibilities—the creation of a new body by independent sponsorship, either with no society participation or with the society's general support. The first of these is rejected because of the high costs arising from the need for administration and accommodation separate from the society and because of the possibility of conflict with the society. In the end, therefore, the working group recommends independent sponsorship with society support.

The working group is now soliciting views from as many geologists as possible, both on the idea of a professional body as such and on the proposed structure as set out in an appendix to the report. Those who respond should pay particular attention to the latter, for experience suggests that detailed organisational points which appear unimportant can, in fact, have profound consequences. For example, the working group suggests, without discussion, that the new institute should "be established as a charitable body"—an apparently innocuous enough statement. But under the present, admittedly chaotic, laws governing charitable bodies in Britain this would prevent the institute from taking part in any activity remotely political. Registration as a charity would therefore place constraints on the institute which are in many ways comparable to those now acting on the Geological Society itself. Would this be in the best interests of the geology profession?

Finally, there is at least one surprising omission from the report. The

working group makes the contentious point that "the science of geology embraces many diverse fields including . . . geophysics . . .", but fails to consider, or even mention, the anomalous position of British geophysicists within the Royal Astronomical Society. Although the working group does not regard itself "in any sense as representative", it would surely have been sensible to have had a geophysical representative of that society on the group right from the start.

Ispra's 'factor up' energy programme

THE energy crisis has done a service to both the solar and hydrogen energy projects at the largest of the European Community's Joint Research Centres, that at Ispra on Lake Maggiore, originally an exclusively Euratom establishment. The aim of the solar work, which was only initiated in 1973, is to probe promising areas not well covered either by industry or national research establishments in member countries, and a substantial increase in funding is expected this year.

The approach may be described as a 'factor-up' programme. Fundamental to work at Ispra is that solar energy—although abundant and nonpolluting—is both diffuse and intermittent. Accepting that it is already possible to heat a house by solar energy—it is being done in the French Pyrenees through air convection generated in hollow blackened walls—Ispra is investigating higher efficiency systems. For domestic heating it is pursuing a plug-in, fixed-angle collector unit (not a house) capable of generating 100° C where preser collectors do not surpass 65° C, large because of heat loss from the surface of the collector. Small scale tests of a method are in progress and these involve adaptation of the 'anti-radiation' cells developed by Francia.

A temperature of 100° C is a threshold value for another small 'domestic' application of special interest in underdeveloped arid regions. "To use the Sun to pump water out of the desert" as the brisk energy director at Ispra, Dr Joachim Gretz puts it. A heat source of this order could be coupled to a 1-kW power set able to pump up water for 8 hours a day (during sunlight) for human and animal subsistence. Dr Gretz points out that in many areas primitive concepts of the natural world mean that communities are dying of thirst while there is pumpable water only 16–60 m down.

Looking further ahead Ispra sees real promise in quantum devices with which yields of 1 kW m⁻² would be possible through photoelectric or photochemical conversion. □

Victimisation

SIR,—In your issue of July 12 you publish the appeal of Dr Peleska, the Czechoslovak scientist, to the World Federation of Scientific Workers.

Unfortunately, the WFSW has many allegations of victimisation against scientific workers brought to its attention, involving many different countries. For example, in the same letter as that in which I reported the receipt of Dr Peleska's letter to the vice-presidents of the federation, I also had to report two other allegations, in some respects even more serious. There was the case of Professor José Ferreira de Alencar, a Brazilian anthropologist and sociologist, who was said to have been imprisoned and ill-treated as a direct consequence of reports he has written on the social status of the people of North-East Brazil. There was also the case of Professor Horst Holzer, one of the leading sociologists in the Federal German Republic, who was dismissed in April 1974 by the Bavarian Ministry for Education and Culture because of his membership of the German Communist Party.

There is no doubt of the policy of the World Federation of Scientific Workers on the question of the right of scientists to work. It is, for example, dealt with in the Declaration on the Rights of Scientists, adopted at the Ninth General Assembly of the Federation in Paris in 1969. Thus:

"3.2. Scientific workers should have the right to work in accordance with their scientific capacities and Governments should endeavour to ensure this right.

"3.5. Scientific workers should have equal rights in their professions, regardless of sex, race, nationality, creed or political conviction."

We have affiliated organisations of scientific workers in 30 countries and they all accept these basic principles of the Federation. When a serious *prima facie* case of victimisation of a scientist is brought to our attention we refer it to our affiliated organisation if there is one in the country concerned, ask them to look into the matter and, where appropriate, either take action themselves or suggest possible action the Federation can take. In some cases in which we have intervened in this way appropriate remedial action has been taken. In other cases new circumstances have been revealed

which have put a different complexion on the case.

It is difficult to see what further action is open to us. The preamble to our Constitution states quite clearly: "The Federation will endeavour . . . to develop relations between scientists having regard to the autonomy of each organisation, to the equality of rights, to the avoidance of interference in the affairs of national organisations." It is difficult to see how an international body could be based on any other principle. Differences of practice between different countries are very great and appropriate allowance must be made for this. Very many useful initiatives have been taken by the Federation and the close contacts maintained between our affiliated organisations in different countries are beneficial to scientists and for science itself. Our aim must be to strengthen these contacts.

Yours faithfully,

E. H. S. BURHOP

Ill reactor?

SIR,—The United Kingdom is now not only a *de facto* but also a *de jure* partner in the Institut Laue Langevin, built around the high flux neutron beam reactor. Since we are equal partners in the running and use of the establishment, we might also claim an equal share in its name. Fortunately, the choice of a suitably alliterative British scientist is obvious. What could be better than to call it the Institut Laue Langevin Lonsdale. Such a choice may be justified on several grounds:

Kathleen Lonsdale was a most distinguished scientist, the first woman elected Fellow of the Royal Society. She was a crystallographer, hence her name has obvious associations with the high flux beam reactor.

Just as von Laue and Langevin, Kathleen Lonsdale was all her life a champion of dignity and freedom.

Changing ILL to ILLL would have the advantage that newspaper headlines could no longer be misunderstood, and there would be no danger of an announcement like "Ill Deputy Director Returning to England" causing anguish to Dr W. M. Lomer's friends.

Yours faithfully,

N. KURTI

Oxford

Anonymous refereeing

SIR,—It seems that the best way to obviate the misuse of the unilateral anonymity granted to reviewers is to extend anonymity to authors as well. When the reviewers get a paper from the editor but have no idea who the authors are or what their affiliation is, they would find less pleasure in making unnecessary and uncivilised remarks. In addition, the reviewers would be able to judge a paper more justly and without prejudice.

This bilateral anonymity programme is simple, and can work. And yet, after this is adopted I should like to go one step further in proposing that all papers be not only reviewed but also published anonymously.

The idea "publish or perish" did stimulate scientific research for a while. But it has now come to the stage where too much energy is wasted in unnecessary publications. I believe most scientists would agree that the total amount of papers published yearly could very well be cut 50% or more without showing any significant impediment in the progress of science. If this immense waste is allowed to continue, the advancement of science will actually be slowing down rather than moving faster. The main reason for this is that we place too much emphasis on the number of papers that a scientist has produced. One obvious result has been much unnecessary repetition.

If all papers were published anonymously, then the "status" of being a prolific writer would be diminished. The fight among authors about whose name should appear first would disappear. The scientific community could, furthermore, judge a paper solely on its merit.

My ultimate hope is to dissociate totally the name from the achievement. If Einstein were alive today, I believe he would not mind if people discussed and utilised the great theory of relativity without mentioning or even knowing his name. But I dare not advocate such a radical proposal at this time. Scientists are human, and as such must be selfish beings after all.

Yours faithfully,

Older comets lose their sparkle

ON each successive approach to the Sun a comet becomes fainter. This phenomenon can be explained as follows. The nucleus of a comet can be considered as a conglomerate of ices and dust, and the regular heating of the nucleus each time the comet moves through the perihelion position of its orbit leads to sublimation of the ices, the copious emission of volatiles, a concomitant loss in mass and either a reduction in the size of the nucleus or the production of a relatively ice-free, porous dusty mantle around the nucleus. Thus, the emission of volatiles decreases each time that the comet goes past the Sun and the maximum brightness of the comet therefore diminishes. Since the 1920s, however, there has been a considerable controversy as to the rate of this secular decrease in brightness. The protagonists today are Sekanina (Smithsonian Astrophysical Observatory, Cambridge, Massachusetts), Vsekhsvyatskij (Astronomical Observatory, Kiev University), and Kresák (Astronomical Institute of the Slovak Academy of Sciences, Bratislava). A recent article by Kresák (*Bull. astr. Insts Csl.*, **25**, 87; 1974) adds fuel to the debate, the main point of which is not the fact that short period comets (those with periods less than, for instance, 20 yr and with a median period of 6.8 yr) are short lived objects in Solar System terms, but whether their decay process has actually been observed as a secular decrease in brightness within the age of accurate astronomical observation, that is, the last century and a half. Sekanina and Vsekhsvyatskij think that decay has been observed; Kresák disagrees.

A principal difficulty is that photometric observations of comets, collected by Vsekhsvyatskij, have been used by other researchers without due consideration of the great hazards involved in comparing observations from different epochs between which instruments and observing techniques have both developed enormously. Use has sometimes been made of visual magnitude data quoted to ± 0.1 mag without any consideration of systematic errors which may amount to many magnitudes (magnitude measures brightness on a logarithmic scale; one magnitude is equivalent to a 2.5 fold change in brightness).

The head of a comet consists of a diffuse coma which surrounds a central condensation or nucleus. Observations made with comet seekers of low focal ratio and moderate magnification, or with small cameras, allow the intrinsic magnitude of the diffuse comet head to be compared with the point images of reference stars, without the introduction of appreciable systematic error. If, however, the focal length and exposure time are increased, the apparent motion of the comet is accentuated and the image is trailed. Furthermore, in a telescope with a long focus a typical comet head of several minutes of arc in diameter may cover the whole visible field of view, adding to the sky background, and leaving only the nucleus to be measured. The luminosity of the nuclear condensation may be as low as 0.1–1% of the total luminosity of the comet. During the past two centuries magnitude estimates using small instruments or the naked eye have been replaced by the application of large telescopes and astro-

photography. That improves the detection limit of point sources but only partially affects the detection of large and diffuse comets.

Kresák illustrates this problem by considering published observations of the 1962 appearance of Comet Tuttle-Giacobini-Kresák, which had a very small nucleus and a large coma. The observations show systematic differences: there is an intensity ratio of 1000:1 between the most divergent observations.

Incompleteness of observations also introduces a difficult problem: for example, the absolute magnitude (the magnitude that the comet would seem to have if it was placed in a standard position 1 AU from the Earth and the Sun) is not the only decisive factor effecting the probability of detection; there are also important geometrical conditions of a seasonal nature. If there is a Gaussian random walk in the absolute magnitude at each return, then the comet will most probably be discovered when the random fluctuation makes it brightest (thus, the first observation is non-typical). Moreover, as observing conditions determine whether or not it will be observed on subsequent returns, the actual observations will be biased. As the limits of detection have decreased with time because of instrumental improvements, minimum values which are detected easily now would, in previous decades, have been missed. Both these effects bias the data towards a rate of absolute brightness decrease which is too steep.

Kresák, using observations of the total brightness of the whole comet head, concludes that the secular decrease in brightness of the periodic Comet Encke is only 1 mag per century and not 3 mag per century, as was found by Sekanina (*Astr. astrofiz.*, USSR, **4**, 54; 1969). And the rate of decrease is not accelerating. Kresák checked his absolute magnitude results by using the maximum visual magnitude at each apparition and obtained a similar decrease.

A rapid secular decrease in the brightness of short period comets would imply that the objects observed today were considerably brighter in preceding centuries, assuming, that is, that they have not in the meantime been captured from orbits of large perihelion distance. Unfortunately, short period comets are mostly too faint to be recorded as naked eye observations in mediaeval ancient records, and Jovian perturbations drastically alter their orbits, which makes backward extrapolation from today's observations exceedingly difficult. One exception is Comet Encke, which has a relatively stable orbit well inside that of Jupiter.

Ho Peng Yoke (*Vistas Astr.*, **5**, 127; 1962) produced a catalogue of ancient and mediaeval Chinese observations. A backward extrapolation of the secular brightness of Comet Encke would imply an easy identification of Encke in Ho Peng Yoke's catalogue; for example, extrapolation using Sekanina's value would make the comet frequently brighter than Venus before 1700. Kresák, however, found no evidence in the catalogue of periodic appearances of Comet Encke, and thus concluded that Sekanina's result is too large.

The high decay rates found by Sekanina and Vsekhsvyatskij have been applied by many authors to predict death dates for individual comets. Kresák shows not only that these projections would remove most of the well observed short period comets from our view within the

next decade or so, but also that many comets are still visible long after their predicted demise, two more facts in favour of a slow decay rate. Vsekhsvyatskij's decay figures of 0.3–0.4 mag per revolution gives short period comets a lifetime of two centuries, and proposed accelerations of this rate reduces this life to a few decades. Kresák finds that during the period 1930–1970 the discovery of short period comets has stabilised at a constant level of seven per decade. This perturbational capture rate is, in fact, no adequate substitute for the rapid loss predicted by Sekanina. If the short period comet population is in equilibrium, Kresák's low values of decay rate must be applicable.

Kresák concludes that the process of ageing of comets, and its effect on the variation in absolute brightness, cannot be satisfactorily explained by a simplified model of continuous mass loss which induces a continuous secular variation in absolute magnitude. Rather, observational evidence suggests strongly that the evolution proceeds stepwise, with short periods of abrupt evolution interspersed with long, relatively latent periods during which the brightness undergoes some fluctuation but in general remains essentially unchanged.

DAVID W. HUGHES

Dirac completes his theory of large numbers

It is not often that a man begins a new physical theory in his thirties, and then returns to finish it off forty years later. In a letter to *Nature* in 1937 (139, 323) Dirac added to his store of brilliant ideas a fundamental hypothesis concerning the values of various naturally occurring dimensionless numbers. In the past two years he has returned to this hypothesis to explore its consequences in detail. His latest article (*Proc. Roy. Soc.*, A338, 446; 1974), deals with certain astronomical and cosmological topics.

Dirac's theory begins with the question: what is the age of the Universe expressed in some naturally occurring units? A fundamental unit of time is the interval required for light to cross a characteristic atomic dimension, say 10^{-13} cm. Then the age of the Universe comes out at about 10^{39} in these units. The significance of this number is that it turns out to be simply related to other large dimensionless numbers formed from astronomical and atomic data; for example, the total number of particles in the observable Universe is around 10^{78} , that is $(10^{39})^2$, and the ratio of the electric to gravitational attraction between an electron and proton, e^2/Gm_em_p , is also about 10^{38} . In view of the fact that the first number obviously increases with time, the coincidences involved by these simple relationships seems great. Dirac's explanation of this curiosity is that all such large quantities are connected, so that as the first increases with time so do the others. This is already a radical departure from conventional physics, which in addition imposes severe restrictions on cosmology. Dirac calls this connection the large numbers hypothesis, in which he expresses "great confidence".

In his 1937 article, Dirac was led by this hypothesis to a model universe which expands with time t like $t^{1/3}$, making it about half as old as the more conventional big-bang models. In his recent work, however, the bald hypothesis is accompanied by a detailed gravitational theory which bears some similarity to the work of Hermann Weyl and E. A. Milne. A central feature of this work is the proposal

that there are really two space-time metrics; one, which is unmeasurable directly, enters into the Einstein equations (which remain valid) and the other is what is actually measured in laboratory experiments involving atomic apparatus. A connection between these two metrics is provided by a consideration of the motion of the Earth around the Sun, which in Newtonian approximation is essentially determined through the relation $GM = v^2 r$ connecting the Newtonian constant of gravitation G with the solar mass M , velocity of the Earth v and radius of the Earth's orbit r .

There then follows an argument which is typical of that used throughout Dirac's work. In terms of Einstein units, the quantities in this equation are constant. But in atomic units one must satisfy the large numbers hypothesis, so that G must decrease as t^{-1} in order that e^2/Gm_em_p increases proportionally to t . Theories involving a changing constant of gravitation are not new: for example, Brans-Dicke theory predicts a similar effect. The change is, however, very small and barely detectable with current technology.

Once again, the number of particles in the Universe $(10^{39})^2$ at present, is required by the large numbers hypothesis to increase as t^2 , which is interpreted by Dirac as a form of continual creation along the lines of the steady state theory.

Two possible creation mechanisms are proposed, with the new matter either appearing concentrated in existing masses (multiplicative creation) or spread out in the intergalactic spaces (additive creation). In the latter case the mass M in the above equation is constant, so that r in atomic units varies like t^{-1} . In the former case $M \propto t^2$ and $r \propto t$. It follows that the ratio of the two metrics can be t^{-1} or t , and that the Solar System must be either expanding or contracting with time.

In terms of Einstein units, if multiplicative creation is adding continuously to the mass M of the Sun, conservation of energy requires that the nucleons in the Sun decrease in mass as t^{-2} to compensate. Through the relation $e^2/Gm^2 \propto t$ this further requires $e \propto t^{-3/2}$ and \hbar (Planck's constant) $\propto t^{-3}$. A number of interesting cosmological consequences follow. First Dirac argues that any universe consistent with the large numbers hypotheses must be static, to avoid the introduction of a characteristic cosmological epoch (that is a constant large number). The red shift of distant galaxies, normally interpreted as a recessional effect, is instead accounted for by the decrease in the unit of atomic time interval. The Universe is prevented from gravitational collapse by the introduction in Einstein's equations of the cosmological constant which may be non-zero for multiplicative creation because of the correct time dependence of the metric ratio in this case. Dirac thus arrives at a version of Einstein's original static model universe.

In the case of additive creation Dirac proposes to conserve energy by the introduction of an unobservable negative energy field spread throughout the Universe, along the lines of the C-field of Hoyle and Narlikar. The total energy density of the Universe thus vanishes, so that the global geometry is just the Minkowski space of special relativity. In comparing the two models, Dirac inclines to the latter, on the basis that the creation of new atoms in existing material would lead to insuperable difficulties concerning the crystalline structure of very old rocks.

Dirac's article is written in his usual lucid and direct style. The ideas it contains, a mixture of old and new, are probably unpalatable for most modern cosmologists. Yet they are the product of a lively imagination, challenging the fundamental principles on which modern theories of astronomy, cosmology and physics itself are founded. Coming from a physicist of Dirac's stature, that is at the very least thought provoking.

P. C. W. DAVIES

Passive transport of insect urine

from our *Insect Physiology Correspondent*

It has long been realised that the Malpighian tubules of insect constitute a filtration-reabsorption system comparable with that of vertebrates. But in the absence of a glomerulus the flow of water is sustained by secretion in the upper region of the tubule, as in the aglomerular kidneys of some fishes, and not by pressure of the blood. Reabsorption of water can occur in the lower segment of the tubules, and in the hindgut and rectum—as in the kidney tubules and cloaca of many vertebrates. As was first shown by Ramsay, the osmotic driving force for the flow of water is produced by the active secretion of ions, particularly potassium; although sodium and chloride can play a part in some insects. The wall of the tubules was believed to be readily permeable to small organic molecules, so that sugars, amino acids and the like entered along with the water; the valuable components were reabsorbed, while toxic materials and waste products were discarded.

This problem of the passive permeability of the Malpighian tubules to organic solutes has now been re-investigated by Maddrell and Gardiner (*J. exp. Biol.*, **60**, 641; 1974) in the blowfly *Calliphora*, the locust *Schistocerca*, the hawk-moth *Manduca* and the blood-sucking bugs *Triatoma* and *Rhodnius*. Some eighteen compounds, labelled with carbon-14 or tritium were used as test substances; mostly amino acids and sugars, but including urea, urea acid

and inulin. Most of the experiments were done on Malpighian tubules isolated *in vitro* in appropriate saline solutions; but the results were confirmed by *in vivo* observations. The concentrations of the test substance in the bathing medium (*M*) and in the secretory product (*S*) were measured, along with the rate of fluid secretion, which could be varied experimentally by appropriate stimulation. It was found that there was always a linear relation between the *M/S* ratio and the rate of fluid secretion—as was to be expected if the transport was purely passive, the slope of the line being determined by the permeability of the tubule to the substance in question. There was thus, for example, a very gentle slope for the small molecules of xylose, as compared with the steep slope for the large molecules of inulin. Highly charged molecules penetrate more slowly than those more nearly neutral electrically: thus L-valine accumulates at one fifth the rate of D-xylose. The permeability of the tubules to such materials as inulin (molecular weight 5,200) is surprising. In some experiments, where the tubules are secreting very slowly, inulin may reach a concentration in the secreted fluid nearly 50% of that in the bathing medium. The authors suggest that much of this passive permeability lies in the intercellular spaces (see figure).

These experiments seem to have established the fact that the content of small organic molecules in the Malpighian fluid is determined by a passive non-discriminatory process. This means that the onus for conservation and discrimination resides in the re-

absorptive system. Here one is less well informed. The reabsorption of ions by the rectal epithelium has been well studied; and some absorption of amino acids and sugars occurs here. But a large part of the reabsorption probably takes place in the Malpighian tubules themselves, notably in the lower segments, and perhaps in the ileum where this exists. Furthermore, not all 'secretion' by the tubules is passive: some materials such as biliverdin, are transported by a process of endocytosis and exocytosis; the excretion of indigo carmine, which was so widely studied in the last century, presents some curious features that are not fully explained.

Modified nucleotides in messenger RNA?

from Alan E. Smith

UNTIL recently it was thought that minor bases were present only in transfer RNA (tRNA) and ribosomal RNA (rRNA), but the difficulties in obtaining sufficient pure messenger RNA (mRNA) prevented definitive analysis of the latter. The presence of poly (A) in mRNA and heterogeneous nuclear RNA (hnRNA) can now be utilised to obtain purified fractions of these species and they can be examined for nucleotide composition without risk of contamination by rRNA and tRNA. In the first issue of *Cell* (**1**, 37–42; 1974), Perry and Kelly reported the results of such an analysis of mouse L-cell mRNA and showed that on average there are about 2.2 methyl groups per 1,000 nucleotides. This compares with about 13 methyl groups per 1,000 in rRNA, and means that an average cellular messenger molecule containing, say, 3,000 nucleotides has about 6 or 7 methyl groups.

hnRNA, on the other hand, contains many fewer methyl groups and Perry and Kelly therefore suggested that in eukaryotic cells methylation like the addition of poly (A) constitutes a post-transcriptional modification of mRNA precursors. These authors, however, did not identify the minor bases present in a specific mRNA species nor did they position them within the molecule.

The first identification and precise location of a minor nucleotide in mRNA has now been reported using a somewhat exotic system. In an elegant paper (*Nucleic Acid Reports*, **1**, 809–822; 1974), Furuichi shows that the mRNA of silkworm cytoplasmic polyhedrosis virus (SCPV) contains a 2'-O-methyl adenylic acid in the 5' terminal position, and that transcription to give mRNA is intimately coupled to the methylation reaction.

SCPV, like reovirus, contains a frag-

Schematic section of the wall of a Malpighian tubule to show the routes of transport of ions and water and diffusion of organic substances through the cell wall. *S/M* is the ratio of concentrations in the secreted fluid and in the bathing medium or haemolymph.

mented double-stranded RNA genome which consists of ten different segments. The terminal nucleotides of the double stranded RNA have recently been reported (*J. molec. Biol.*, **85**, 31–48; 1974) and the 5' nucleotide sequence of one strand of each of the segments is A*GU, where A* is a methylated adenosine. SCPV contains a virion-associated transcriptase which transcribes all ten double stranded RNA fragments *in vitro* to give mRNA molecules each of which begins with a 5' terminal sequence ppAG (*J. molec. Biol.*, **85**, 21–30; 1974; see also *Nature*, **250**, 13–14; 1974).

Since the activity of the SCPV transcriptase is low compared with that of the enzyme from reovirus, and because the genomic RNA is methylated, Furuichi tried adding a donor of methyl groups to the *in vitro* reaction mixture, and observed a huge stimulation of mRNA synthesis on addition of S-adenosyl-methionine (SAM). The product formed *in vitro* was found to be virus-specified and consisted of complete copies of one strand of each of the genome segments containing, on average, one methyl group per RNA molecule. The methyl group incorporated into the viral mRNA was detected in 7-O-methyl adenylic acid which is also present at the 5' terminus of the genomic double stranded RNA.

Furuichi examined the RNA made during very short incubations and found that methylation occurs early in the transcription process when the nascent chains are less than ten residues long. Since mRNA synthesis is almost totally dependent on addition of the methyl donor, and methylation is such an early event, Furuichi suggests that methylation may be involved in the initiation of mRNA synthesis and that SCPV transcriptase utilises a methylation-coupled transcription system, which is so far unique.

It will be of interest to establish whether other viral transcription systems are similarly coupled. It is already known, for example, that the RNA tumour viruses contain virion-associated methylase enzymes, as well as reverse transcriptase. So far the effect of SAM *in vitro* has not been reported in this system.

Of even greater interest will be an understanding of the initiation of hnRNA synthesis in normal cells. Bajzar, Samarina and Georgiev (*Molecular Biology Reports* **1**, 305–310; 1974) have isolated the 5' terminal nucleotides of mouse cell hnRNA and identified them as pppAp and pppGp. So far there is no evidence for methylation in these positions. It is possible, however, that methylation occurs at internal positions in hnRNA and that such modifications act as markers for subsequent cleavage reactions. It may be significant that

the chromatographic mobility of some of the methylated nucleotides detected by Perry and Kelly in mouse mRNA suggested that more than one phosphate group is present. Perhaps some of the methyl groups are attached to nucleotides (pX*p) which originate from the 5' end of mature cellular mRNA.

Models of magnetic anomalies

from Peter J. Smith

A MAGNETOMETER towed at or near the ocean surface will record the well known linear magnetic anomalies which arise from alternating normal and reversed magnetic material within the oceanic crust. A magnetometer towed along very close to (say, within 100–200 m) of the sea floor, on the other hand, records anomalies which are much narrower and yet much greater in amplitude. But to what is this fine structure due? Do these small scale variations within magnetic polarity epochs and events reflect real physical variations of internal crustal properties or are they merely the result of topography or some other equally uninteresting phenomenon?

Conclusions on this point seem to differ. Atwater and Mudie (*J. geophys. Res.*, **78**, 8665; 1973) measured near-bottom anomalies on the flank of the Gorda Rise and found that almost all of them could be accounted for by a uniformly magnetised basement with topography. But some years ago, Luyendyk (*J. geophys. Res.*, **74**, 4869; 1969) found such an explanation unsatisfactory in connection with the fine structure in an area on anomaly 10 west of southern California. Instead, he invoked variations in magnetisation which arise either from ancient magnetic field variations or changes in petrology with distance from the ridge crest. Similarly, Larson and Spiess (*Science*, **163**, 68; 1969) concluded from a profile across the East Pacific Rise crest that small scale anomalies within the Brunhes epoch are unrelated to basement topography, and again appealed to fluctuation in palaeointensity.

Insofar as these conclusions refer to difficult areas they are not necessarily inconsistent, for it is quite conceivable that apparently similar phenomena in different regions could be explained in different ways. On the other hand, it is clearly important to know whether a common observation may be dismissed as an effect of little significance or whether it is necessary to look for deep-seated physical causes. So to investigate this matter further, Larson *et al.* (*J. geophys. Res.*, **79**, 2686; 1974) have constructed and analysed magnetic

block models based on the volcanic basement profile actually obtained across the East Pacific Rise by Larson and Spiess—a profile carefully obtained by continuously and simultaneously measuring the depth of the magnetometer with an up-looking sonar, the height of the instrument above the sea floor with a down-looking sonar, and the thickness of sediment with another down-looking sonar.

The first model was given a constant magnetisation of 0.011 e.m.u. cm⁻³ to see if such uniformity could reproduce the observed magnetic anomalies. As far as general widths and amplitudes were concerned, agreement between model and observation was quite good; and some specific anomalies were particularly well matched. In such cases it follows that the relevant near-bottom anomalies may be accounted for solely in terms of the shape of the basement profile and variations in the magnetometer depth. But in many cases specific anomalies were reproduced poorly by the uniform model, notwithstanding its topography. For such anomalies good agreement between model and observation could only be obtained by allowing magnetisation to vary along the profile between extremes of 0.0048 and 0.0257 e.m.u. cm⁻³.

In summary, then, it would seem that however valid were the conflicting conclusions of Luyendyk and Atwater and Mudie in their respective geographic contexts, neither party is completely correct in general. Moreover, it is now clear that Larson and Spiess were not entirely correct in the specific case of the East Pacific Rise in attributing small scale magnetic anomalies solely to lateral variations of magnetisation. Near-bottom anomalies apparently have no unique cause; in any given instance it may be necessary to invoke both topographic and magnetic effects.

Antitumour immunity

from A. J. S. Davies

THE antagonists of the notion of an immunological antitumour defence mechanism very properly ask why the process involved seems so often to fail. The explanations are increasingly ingenious. Initially, antibody was thought to block the response of hostile lymphocytes to the antigenic tumour; then antigen-antibody complexes and finally antigen have become popular as the blocking factor. It is not too difficult to envisage that antibody would mask those sites on the tumour cell which would otherwise act as recognition foci for lymphocytes. The antibody component of an antigen-antibody complex could do the same as long as it has some free binding sites (that is, the

complexes are in the presence of an excess of antibody). Antigen either free or complexes in antigen excess could presumably combine with any lymphocytes capable of reacting against the malignant cells, thus frustrating their attack.

Overall there is the possibility that some central paralysis of the immune response arises which does not operate by one of the mechanisms already considered. This last possibility is not deemed likely as in many of the instances in which a tumour is growing it is possible to detect by *in vitro* methods the existence of cytotoxic cells and antibodies which have some degree of specificity for the relevant tumour. There is a variety of other explanations which involve non-specific suppression of immunological responses particularly in terminal cases as a consequence of the poor physical condition of the tumour-bearing host.

Hattler and Soehnlen have illustrated the operation of one of these mechanisms (*Science*, **184**, 1374; 1974). These investigators cultured the blood lymphocytes of cancer (usually squamous cell carcinoma of the lung) patients together with their irradiated tumour cells and measured the response of the lymphocyte populations by their capacity to incorporate tritiated thymidine some days later. The response was in all instances much improved by washing the lymphocytes five times before they were allowed to make contact with the tumour target cells. This result is reminiscent of those of Curry and Basham (*Br. J. Cancer*, **26**, 427; 1972) who found that in melanoma patients it was difficult to detect the cytotoxicity of lymphocytes against their specific target tumours unless the lymphocytes were washed six times before the *in vitro* test.

The cell wash eluates of Hattler and Soehnlen effectively inhibited the performance of the cells washed five times but failed to influence the (poor) response of cells washed only once. Fractionation of the eluates yielded a low and a high molecular weight entity neither of which was a particularly effective inhibitor but which in combination did inhibit the cells washed five times. The authors suggest that their results are compatible with the notion that the lymphocytes of the cancer patients may be blocked by antigen-antibody complexes. *In vitro* these complexes can be eluted from the lymphocytes permitting the demonstration of specific antitumour responsiveness. The further exercise of fractionation and the demonstration of two component inhibitors certainly seem to support this idea.

The work of Curry (*Br. J. Cancer*, **28**, 153; 1973) again amplifies the concept. In extension of his earlier studies,

Curry found that the serum of patients with extensive malignant disease contained a blocking factor of low molecular weight which had affinity for lymphocytes but not for tumour target cells. In the serum of patients with less extensive tumours the blocking factor was of large molecular weight and had affinity for both lymphocytes and tumour cells. Curry supposed that this smaller blocking material was antigen and the larger antigen-antibody complexes.

These kinds of studies are extremely valuable in pointing to the complexity of antitumour immunity. A complexity which, without considerable luck, must be mastered before effective and rational immunotherapeutic procedures can be adopted.

Alpha A and beta S

from a Correspondent

INTEREST in the detailed mechanism of the aggregation of deoxy sickle-cell haemoglobin (Hb-S) continues to stimulate the application of new experimental approaches. Wilson, Luzzana, Penniston and Johnson (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 1260; 1974) have used the quasi-elastic light scattering method to study the pregelation aggregation of deoxy Hb-S, and obtain results consistent with a linear association between aggregates. This scheme implies that deoxy Hb-S molecules are bifunctional, with respect to aggregation, and interact in a non cooperative manner, rather than by a concerted scheme in which monomers rather than aggregates are in equilibrium with the gel. Both these alternatives have been considered in previous discussions of the sickling process.

Benesch, Benesch and Yung (*ibid.*, 1504) have exploited their earlier success in the specific pyridoxylation of either the α or the β chains of normal adult haemoglobin (Hb-A) to show that substitution of the N-terminal groups of Hb-S inhibits gelation and increases the solubility of the deoxy form. Modification of the α chains has much more effect than that of the β chains, to an extent equal to that produced by dilution of Hb-S with an equal amount of Hb-A. If this effect could be achieved in the intact red cell, it would be equivalent to reducing the sickling tendency from the degree found in homozygous sickle-cell anaemia to the lesser extent experienced in the heterozygous trait condition. Surprisingly the α -chain modified form of Hb-S obtained by using pyridoxal 5'-phosphate, viz. $(\alpha^{PLS})_2\beta_2^S$ scarcely differs from Hb-S itself in its oxygenation parameters, and the decreased gelling tendency must, therefore, be caused

by changes in the structure of the deoxy form *per se*.

The same strategy of selective irreversible pyridoxylation of α or β chains has been used by Suzuki, Benesch and Benesch (*Biochem. biophys. Acta*, **351**, 442; 1974) to demonstrate that the Bohr effect in Hb-A is reduced in both α -chain and β -chain pyridoxylated Hb-A, but to a greater extent in the species with modified α chains. It is known from previous work that about one-half of the oxygenation-linked proton exchange of the Bohr effect is associated with the C-terminal β -146 histidines, and about one-quarter with the N-terminal amino groups of the α chains. Elimination of the ionisable protons of these α -chain N-terminal groups by pyridoxylation can account for the observed diminution of the Bohr effect. For the β -chain modified species there is no elimination of an existing Bohr proton binding site, so the change is probably caused by the introduction of a new ionising group whose acid strength decreases with oxygenation, possibly the 5'-phosphate of the attached pyridoxal phosphate reagent used to prepare the β -chain modified species, and which is presumed to form a salt bridge with β -82 lysine in the deoxy but not in the oxy conformation. On oxygenation this residue would therefore bind protons, accounting for the observed decrease in the Bohr effect. These two papers provide an excellent example of the way in which specifically modified but still functional haemoglobin species provide powerful tools for elucidating details of structure-function relationships.

Finally a paper concerned with the red cell itself, and of particular interest in that it deals with the study of individual red cells, always an approach that appeals to biologists and haematologists, who are concerned with red cell populations rather than haemolysates prepared from millions of cells. Brunori, Giardina and Antonini (*J. molec. Biol.*, **86**, 165; 1974) have studied this distribution of the three major haemoglobin parts of trout (*Salmo gairdneri*) blood by single-cell spectroscopy. They find that the erythrocytes contain the component (Hb-IV) which is characterised by the Root effect in the same proportion as in a haemolysate, and which is therefore uniformly distributed. The Root effect (*Biol. Bull.*, **61**, 427; 1931) refers to a very marked dependence of the oxygen binding curve on pH, such that below pH 7 the haemoglobin is only partially saturated in air. It is characteristic of teleost fish haemoglobins, and related in some way to the mechanism of gas secretion into the swim bladder. Brunori *et al.* speculate that the synthesis of several different normal

haemoglobin components in definite proportions in all erythrocytes may be required to maintain a functional situation dependent on a balance of properties of the various components.

J-dependence in nuclear reactions

from P. E. Hodgson

THE general character of the differential cross sections of direct one-nucleon transfer reactions is dominated by the orbital angular momentum L of the transferred particle. Except at low energies when the angular distributions are backward-peaked and similar for all L values, the angular distributions are peaked at an angle in the forward hemisphere that increases with the value of L . In most cases a comparison between the experimental data and distorted wave calculations enables the value of L to be determined.

Since the transferred nucleon also has a spin of $\frac{1}{2}$, the total transferred angular momentum J is the vector sum of L and $\frac{1}{2}$, and since these can be added or subtracted, $J=L\pm\frac{1}{2}$. If the target nucleus has zero spin, this J is just the spin of the final state of the residual nucleus.

The angular distributions of reactions of the same L but different J are usually very similar, but in some cases small but systematic differences have been found. These are called the J -dependent effects, and have proved quite useful in assigning spins to nuclear states simply by the shape of the angular distribution, without any detailed calculations.

These J -dependent effects depend on the transferred orbital angular momentum L and on the incident energy, and are more marked in some cases than in others, so it is clearly important to understand how they arise, both for their intrinsic interest and in order to enhance their utility in nuclear spectroscopy.

The most marked J -dependent effects are found for $L=1$ transitions, and Robson has shown that these can be accounted for very well by distorted wave calculations with a spin-orbit interaction in the incoming and outgoing channels, provided the optical potentials are chosen to fit both the differential cross section and the polarisation of the corresponding elastic scattering.

For $L=2$ and 3 the J -dependent effects cannot be accounted for in this way and several attempts have been made to develop the distorted wave theory, in particular by including the deuteron D-state. This is a complicated calculation, and some of the results show J -dependent effects that are similar to those observed. The difficulty of the calculations has however deterred

an extensive study, so most of the J -dependent effects remain unexplained.

Quite recently a new explanation of J -dependent effects has been proposed: they are attributed to the contributions of two-step processes to the reaction amplitude. The importance of two-step processes is now widely known, especially when the nuclei are deformed and when the direct one-step transition is forbidden or inhibited by some selection rule. A substantial proportion of the reaction can proceed by the incident particle first exciting the target nucleus to a low-lying collective state by inelastic scattering, followed by the particle transfer to the final state. Similarly, the particle transfer can take place first to the ground or to an excited state of the residual nucleus, which can then be excited to the final state by an inelastic process as the outgoing particle leaves. All possible processes of this type combine to give the observed cross section.

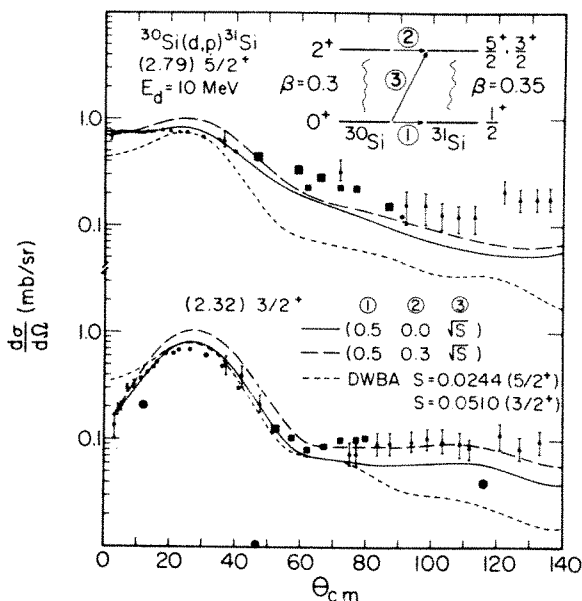

In recent years the formalism for calculating such processes has been extensively developed, and many studies have shown the importance of including two-step processes. It has now been applied by Hoffmann, Udagawa, Coker, McIntyre and Mahlab (*Phys. Lett.*, **50B**, 249; 1974) to study the J -dependent effects in the reaction $^{30}\text{Si}(\text{d},\text{p})^{31}\text{Si}$ at 10 MeV to the 2.32 MeV ($3/2^+$) and 2.79 MeV ($5/2^+$) states of the residual nucleus. As the figure shows, the cross sections of these two reactions differ markedly in the forward direction, although they are both $L=1$ and very similar in energy. The short-dashed curves are standard DWBA calculation, which gives very similar angular distributions for the two reactions, and does not account at all for the difference between them. The calculation including the two-step process via the

$1/2^+$ state of ^{31}Si at 0.75 MeV gives the full curves, which are in excellent accord with the data in the forward direction. The small differences in the backward hemisphere are probably attributable to compound nucleus contributions. A final calculation including those two-step processes through the lowest 2^+ state of ^{30}Si gave the long-dashed curves which do not agree with the data, which is expected since the excited states of the two states of ^{31}Si have a small parentage in terms of the 2^+ state in ^{30}Si , so that this process does not contribute significantly to the reaction.

Inclusion of the two-step contribution to this reaction is thus able to give a very good account of all the J -dependence of the cross sections to the $3/2^+$ and $5/2^+$ states of ^{31}Si . Other effects, such as those caused by the deuteron D-state, may contribute, but in this case at least they are small.

Further calculations by Coker, Udagawa and Hoffmann have shown that the two-step process is also able to account for the $L=2$ J -dependent effects in the $^{28}\text{Si}(\text{d},\text{p})^{29}\text{Si}$ reaction at 10, 13 and 18 MeV to several final states.

This work shows that two-step processes via low-lying collective excitations account for some of the J -dependent effects in one-nucleon transfer reactions in deformed nuclei. The J -dependent effects, however, are also found for nuclei to which this explanation cannot apply. It is therefore necessary to carry out a series of analyses for a range of nuclei and incident energies for different L -values with consistent parameters for the distorting potentials. This will make it possible to establish in a systematic way the contribution of two-step processes to J -dependent effects in nuclear reactions.

Differential cross sections for the one-nucleon transfer reaction $^{30}\text{Si}(\text{d},\text{p})^{31}\text{Si}$ at 10 MeV to the 2.32 MeV $3/2^+$ and 2.79 MeV $5/2^+$ states of ^{31}Si compared with distorted wave calculations. The short-dashed curves are the simple one-step calculation and the full curves show the effect of including the two-step process (1). The long-dashed curves show the effect of including the coupling (2) between the excited states, which does not contribute significantly. The figures in the brackets are the spectroscopic factors for the various transitions.

Deterioration of high school students' attitudes to physics

Paul L. Gardner

Faculty of Education, Monash University, Clayton, Victoria 3168, Australia

Australian students taking a physics course based on PSSC displayed a sharp decline in enjoyment of physics. Pupil personality and teacher behaviour variables affected the extent of this decline.

SCIENCE teachers are still concerned about the attractiveness of physics courses. In 1971, in Victoria, Australia, high school physics enrolments showed an absolute decline for the first time in recent history, and a further decline occurred in 1972. In Britain, 2,400 university science places were unfilled in 1973-74, and a complete halt in all university science building programmes for a decade has been predicted¹. Hopes for large increases in the proportion of girls taking physical sciences² have not materialised. There have been attempts to explain this in terms of the poor 'image' of physics and physicists³, a modern distaste for science and technology⁴, the failure of physics curricula to include social aspects of science which are of interest to adolescents, particularly girls³, and the operation of economic forces outside the control of the science teacher⁵.

The classroom and the people within it, however, probably remain the central arena of interest for the science education researcher seeking to explain attitudes to science and enrolments in science subjects. There have been many searches for relationships between attitudes or enrolments and other pupil and teacher variables. In most of these studies pupil or teacher variables (but not both simultaneously) have been correlated with pupil outcomes. Although such studies are often interesting they do not permit investigations of the complex interactions which may exist between pupil and teacher variables.

Physics questionnaire research study

The physics questionnaire research study (PQRS) project was set up to investigate the relationships between pupil personality, teacher behaviour and pupils' attitudes to physics. The study was done in Victoria, Australia on Grade 11 pupils taking the first year of a 4 yr course based on the United States PSSC materials. To exert a moderate amount of control over a number of extraneous but potentially influential variables, such as school facilities and home background, the sample was restricted to pupils in coeducational State high schools in the more affluent areas of Melbourne.

Three instruments were used in the project: the physics attitude index (PAI) was employed as a pretest and 8 months later as a post-test; the personal preference index (PPI) and the physics classroom index (PCI) were given as mid-tests. A total of 1,014 students (798 boys, 216 girls) in 58 classes in 34 schools were studied.

The PAI is a 40-item Likert-type scale, yielding scores on four attitudes: first, towards unauthoritarian modes of learning; second, towards physics as an open, flexible, dynamic discipline; third, towards scientists, and fourth, per-

sonal enjoyment of physics. The pretest and post-test means⁶ reveal a favourable initial attitude towards active, participatory modes of learning, an attitude which was maintained during the year. The students also entered the course with the view that physics is an open discipline; at the end of the Grade 11 year, their attitude was less open, the difference being statistically significant, although rather small. The students also held a favourable view of scientists as fairly normal people; again, there was a significant although small decline during the year. The most striking finding, however, was on the fourth scale: although on entry to the course, students expressed a high level of enjoyment in learning physics, eight months later their attitude had declined sharply. Since most science educators would want students to increase, or at least maintain, their interest in a subject, this decline in enjoyment is disturbing.

From the PCI and PPI data some inferences may be drawn about pupil and teacher variables which affect this decline. The theoretical framework underlying the two instruments is the needs-press model of Murray⁷ and Stern⁸. The model indicates that human behaviour may be understood in terms of an interaction between aspects of personality ('needs') and relevant aspects of the social environment ('press'). The PPI contains eight needs scales, taken from Stern's Activities Index: achievement; conjunctivity; deference; play; understanding; order; nurturance and energy. The PCI was devised especially for the PQRS project, and contains eight press scales which correspond to these needs: competitiveness; organisation; compliance; pleasure; intellectualisation; compulsiveness; warmth and stimulation.

A 4×4 analysis of covariance design, with an unweighted means adjustment for unequal cell frequencies, was devised to analyse the data. The analysis of the effects of competitiveness and achievement on enjoyment illustrate the design. Class mean scores on the PCI scale were used to divide the 58 classes into four approximately equal quartile groups, each containing either 14 or 15 classes: classes with teachers regarded as very high, high, low, or very low on competitiveness. Individual scores on the corresponding PPI scale were then used to divide the 1,014 students into four approximately equal quartile groups: very high, high, low, or very low on achievement. The covariance design permitted inferences to be drawn about the effects of these pupil and teacher variables on pupils' post-test attitudes, over and above any effects which could be ascribed to attitudes already present at the start of the course. This type of analysis was carried out 32 times to study the effects of eight needs-press combinations on each of the four attitude variables.

Findings

Of the 64 possible main effects, 25 were significant beyond the $P=0.05$ level, and of these 18 were significant beyond the $P=0.01$ level. Some further details of the findings may be found elsewhere⁹. The teachers' behaviour was found to have little effect on pupils' attitudes to nonauthoritarian

modes of learning. There was a weak inverted U-shaped relationship between attitude scores and teacher compulsiveness (that is, the tendency to organise meticulously the physical environment of the classroom.) Three personality variables were found to be significant: students who are motivated by achievement, serious (low on play) and intellectual (high on understanding) display more favourable attitudes. Factor analysis reveals that these personality variables all lie on one factor. Warm and outgoing students (high on nurturance) also display a more favourable attitude: 'discovery' learning, as it is organised in typical schools, generally requires cooperation with other people, and it is perhaps not surprising that students who are personally more outgoing should enjoy it more than students who are less interested in other people.

Students' views concerning the openness of physics were significantly related to only a small number of the predictor variables. Pupils motivated by achievement tend to hold a more open view, but achievement-pressing teachers (high on competitiveness) tend to promote a more closed view. Apparently, teachers who place heavy stress on achievement, success and examination performance are less likely to maintain the highly open attitudes that most of their students have on entering the course. The only other highly significant finding was the positive relationship between nurturance and openness: apparently, warmth towards other people and receptivity to new ideas are related qualities.

Fig. 1. Enjoyment of physics at end of year by serious and playful pupils under four levels of teacher behaviour. *a*, 'Serious' pupils (below median on play); *b*, 'playful' pupils (above median on play).

Students' attitudes towards scientists were strongly related to only two of the predictor variables: deference and nurturance (factor analysis indicates that these two personality variables lie on a single factor). Thus, pupils who are warm and friendly, and who are more likely to be submissive and conformist, are more likely to regard scientists with affection and tolerance. The relationship is sex-linked: girls significantly outscore boys on the two personality variables and on the attitude scale.

The enjoyment of physics scale displays the most significant findings, and nearly all the predictor variables are involved. In general, intellectually intense pupils—those who are serious, intellectual and motivated by achievement—and pupils who are warm and deferent tend to enjoy

physics more. Intellectually stimulating teachers—those who are intellectual, cognitively well-organised (high on conjunctivity), stimulating and achievement-pressing, and whose classrooms are physically well-organised—tend to be associated with greater enjoyment. Analysis shows that students who are intellectually intense with teachers who are intellectually stimulating display a highly favourable initial attitude, and this is maintained during the year. This is a rather small group: about 6% of the sample (the top quartile group of students in the top quartile group of teachers). Other students with other teachers display a greater or lesser decline. If maintenance of enjoyment is the criterion, the course is effective for a very small group of pupils.

The effects of teacher competitiveness are interesting for two reasons: first, because here is a teacher characteristic which tends to promote one desirable objective (enjoyment) while at the same time hindering slightly the attainment of another (openness); second, because there is an intriguing interaction effect with the corresponding pupil personality variable. Details are given elsewhere¹⁰; briefly, highly achievement-pressing teachers exert a beneficial influence on the enjoyment of highly achievement-motivated pupils, but a relatively deleterious effect on the enjoyment of pupils who are very low in achievement motivation.

Teacher pleasure and pupil play also exert interactive effects on enjoyment. As can be seen from Fig. 1, 'serious' pupils (those below the median on play) enjoy physics more than 'playful' pupils. Teachers in the top three quartiles on pleasure have no influence on enjoyment, but teachers in the lowest quartile—very serious teachers—exert diametrically opposing effects upon the enjoyment of serious and playful pupils. Had only class means been considered in this study, no relationship between teacher pleasure and enjoyment would have been found: the correlation between the class means was near zero.

Implications

The PAI has been used in earlier research to compare the outcome of different curricula in other Australian states¹¹. The magnitudes of the teacher behaviour and pupil personality effects found in the PQRS project are much larger than the effects associated with different curricula. Although teacher behaviour is probably more difficult to change than instructional material, the PQRS findings suggest that science educators who wish to bring about improvements in pupil's enjoyment of science subjects ought to concentrate more heavily upon teacher education. The current decline in support for nationally funded science curricula, and the concomitant growth of interest in the pre-service and in-service education of teachers reflect shifts of emphasis which seem to be appropriate.

Palindromic base sequences and replication of eukaryote chromosome ends

T. Cavalier-Smith

Department of Biophysics, University of London King's College, 26-29 Drury Lane, London WC2, UK

A new theory is proposed to explain the synthesis of the 5' ends of linear DNA molecules. It suggests that chromosome ends consist of palindromic base sequences. These can form self-complementary hairpin loops, which can be converted by DNA ligase, a specific endonuclease, and DNA polymerase, into completely replicated ends.

DURING DNA replication, new DNA is made by DNA polymerases which add new nucleotides to the 3'OH end of growing polynucleotide chains. All known DNA polymerases are able only to extend existing polynucleotide chains and cannot start new ones. For this reason, the mechanism of initiation of new polynucleotide chains has for many years been a fundamental problem in the study of DNA replication¹. There is now good evidence that prokaryotes, eukaryotes and viruses all use a short RNA molecule as a primer for the initiation of new DNA molecules^{2,3}; this RNA primer is probably subsequently removed by nucleases³ before the completion of the daughter molecule by DNA polymerases and DNA ligase. The discovery that the transiently-formed, short pieces of DNA known as 'Okazaki pieces' have a short stretch of RNA⁴ at their 5' phosphate ends, strongly supports Okazaki's model⁵ for the discontinuous synthesis of DNA. This model, in which 'Okazaki pieces' are subsequently joined by DNA ligase to form a complete daughter strand, can now (in conjunction with the idea of RNA primers) provide a satisfactory explanation for the mechanism of replication of circular DNA molecules, though details, especially of the control mechanisms, remain to be filled in.

For linear DNA molecules, however, a fundamental problem remains. Watson⁶ has pointed out that when a linear virus chromosome replicates, the excision of the RNA primers from the 5' ends of the two daughter strands will leave a gap which cannot be filled in by DNA polymerase because there is no adjacent 3'OH end to serve as a template (Fig. 1a). Clearly this problem does not arise in the case of a circular chromosome which has no ends. This may be the reason why bacterial and viral chromosomes are often circular: linear chromosomes require a special mechanism for the replication of their ends. Watson suggested two such mechanisms. Circularisation as occurs in λ phage of *Escherichia coli*, and concatemericisation as in phage T7. Both mechanisms require identical sequences at the two ends of the molecules (terminal redundancy). Watson postulated that all linear DNA molecules must be terminally redundant and must replicate either by circular or concatemeric replicative intermediates.

Here I propose a third mechanism for the replication of the ends of linear DNA molecules which allows them to replicate as linear molecules and does not necessarily require terminal redundancy, circular intermediates, or concatemers. I argue that this third mechanism is more likely to apply to eukaryote chromosomes, which are probably essentially single DNA molecules, than either of

Watson's mechanisms. My theory has the added advantage that it can explain several long known, but hitherto unexplained, properties of the ends (telomeres) of eukaryote chromosomes. As it does not necessarily require terminal redundancy and circular or concatemeric intermediates, it may also be applicable to virus chromosomes, such as chick embryo lethal orphan virus⁷, which seem to lack these properties.

Replication of eukaryote chromosome ends

There is increasing evidence that each eukaryote chromosome consists of a single DNA molecule⁸⁻¹¹. Each chromosome contains many tandemly arranged units of replication (replicons)¹², and each replicon is comparable to the whole chromosome of a bacterium or a virus in that its replication is usually bidirectional. The simplest assumption compatible with the genetic evidence for linear linkage groups is that each chromosome is a linear, rather than a circular, DNA molecule. This means that exactly the same problem of completing the 5' ends of daughter strands will arise as in linear virus chromosomes. The basic problem in applying either of Watson's two suggestions for viruses directly to the replication of eukaryote chromosomes is that, if eukaryote chromosomes consist of single DNA molecules, these will often be many thousands of times longer than those of viruses. Because of the consequent considerable reduction in the effective 'concentration' of free ends, the chances of their ever meeting and pairing, whether to form circles or concatemers will be drastically reduced. The mechanism proposed here overcomes this problem.

The central assumption of my theory is that the nucleotide sequences at the ends of eukaryote linear DNA molecules are palindromic, that is if one always reads with the same polarity, the sequence of bases in one strand is

Fig. 1 *a*, The two daughter molecules which result from the replication of a linear DNA molecule, showing the gaps at the 5' end of the newly synthesised strands left by the removal of the RNA primers (the 3' end of a polynucleotide is shown by an arrow, newly synthesised DNA by a thin line). *b*, A terminal palindromic sequence. The sequence on each strand is the same when read with the same polarity.

Fig. 2 Model for the synthesis of 5' ends of a daughter DNA molecule (the 3' end of a polynucleotide shown by an arrow, newly synthesised DNA by a thin line). *a*, Gap at 5' end of new DNA; *b*, The self complementary 3' terminal strand of the palindromic sequence base pairs to form a hairpin loop; *c*, 3' OH end serves as a primer for a DNA polymerase to fill in the gap; *d*, DNA ligase seals the remaining nick; *e*, A sequence specific endonuclease nicks the old strand; *f*, The loop unfolds; *g*, DNA polymerase completes the old strand with new DNA. Note this effectively results in the exchange of new and old DNA at one end of every chromosome.

the same as that on the other (Fig. 1*b*), so that the terminal region as a whole has twofold rotational symmetry.

Because of this symmetry the first base in the sequence on one strand is complementary to the last base on the same strand, the second base is complementary to the last but one and so on. This means that the unreplicated single stranded 3'OH end of a daughter chromosome can fold back on itself to form a terminal base-paired loop (Fig. 2*b*).

I suggest that this is the first stage in the replication of the end of the molecule. Subsequent steps are: the closing of any remaining gap by DNA polymerase (Fig. 2*c*); the sealing of the remaining nick by DNA ligase (Fig. 2*d*); the cleavage of the opposite strand by a sequence specific endonuclease (Fig. 2*e*) (this provides a new 3'OH end which serves as a primer for the final step); the unpairing of the loop to provide a template for the final step (Fig. 2*f*); and finally, the completion of the remaining strand by DNA polymerase (Fig. 2*g*).

The mechanism has only two special requirements: a palindromic terminal sequence, and an endonuclease which can recognise one end of this sequence and cleave the correct strand. Both assumptions should eventually be able

to be tested. Palindromic sequences and endonucleases which recognise them are well established in the restriction mechanisms of bacteria¹³. Perhaps they were ancestral to the mechanism postulated here. The palindrome need not be perfect since there must be at least two bases at the end of the loop which cannot pair and therefore need not be complementary.

Telomeres of eukaryote chromosomes

Although eukaryote chromosomes probably consist of a single DNA molecule, very little is known of the way this is folded in mitotic and meiotic chromosomes. In particular, it is not known whether the two ends of the molecule lie at the ends (telomeres) of the chromosome. In the case of meiotic chromosomes, however, the correlation in maize between the linear sequence of chromomeres and the linear sequence of genes in a linkage group makes it reasonable to assume that this is the case. If, therefore, one assumes that, as a general rule, the ends of the DNA molecule do in fact form part of the telomeres then the existence of terminal palindromic sequences could explain several intriguing properties of the telomeres.

First, there is evidence that broken ends of chromosomes behave differently from the natural ends in that they are 'stickier' and have a strong tendency to rejoin or to become permanently joined to broken ends of other chromosomes¹⁴⁻¹⁶. This is to be expected because broken ends are probably often single stranded, and if they contain partially complementary sequences (for example, one of the widely dispersed repetitive sequences¹⁷) or precisely complementary sequences (as in rejoining) can base pair and be irreversibly joined by polymerase and ligase action. By contrast, telomeres could not become permanently joined because of the sequence-specific endonuclease which would split them apart, if they did happen to pair and become joined when in the single stranded state.

A second property of telomeres is frequent temporary association of the telomeres of homologous chromosomes^{18,19}. Even in the absence of palindromic ends, the corresponding ends of homologous chromosomes could associate by 'side-to-side' base pairing if the appropriate strand of each is incomplete (whether because of exonuclease digestion or the delayed completion of replication, Fig. 3*a*). The existence of terminal palindromic sequences, however, would provide an alternative explanation. 'End-to-end' pairing to form a circular dimer would be possible if the 5' ends of the two homologous chromosomes were partially digested by exonuclease action (Fig. 3*c*). Indeed, this would provide an alternative pathway for the replication of 5' end if gaps in this dimer were repaired by DNA polymerases and ligase and then staggered nicks inserted (Fig. 3*d-e*), and the replication completed as before by DNA polymerase. This pathway, in contrast to the previous one, would be most efficient if the palindrome was perfect, since all nucleotides could take part in base pairing.

The occurrence of pairing between homologous telomeres in either of the two ways suggested here could explain cases of late separation of telomeres in mitosis²⁰.

In meiosis, the telomeres normally form strong end-to-end attachments at the beginning of diakinesis^{15,19,21}. Darlington's theory of the terminal chiasma²¹ postulated that this 'terminal affinity' was quite distinct from the normal lateral pairing of chromosomes during the earlier stages of meiotic prophase. I suggest that terminal affinity could be caused by the end-to-end association of palindromic ends as shown in Fig. 3*d*.

Nonhomologous chromosomes

Although the replication mechanism postulated does not require terminal redundancy, and would work perfectly

well even if the palindromic sequences at the two ends of a chromosome were different, there seems no obvious reason why they need be different. So it would be simplest to assume that the telomeres of all chromosomes in any one eukaryote are identical. The considerable evidence for

Fig. 3 *a*, Delayed replication provides a simple explanation for the late separation of telomeres at anaphase, which does not require palindromic sequences (the 3' end of a polynucleotide shown by arrow, newly synthesised DNA by a thin line). *b-g*, An alternative model for the replication of 5' ends and the delayed separation of telomeres. *b*, Gaps at 5' ends left by removal of RNA primer; *c*, an exonuclease digests the 5' ends of old DNA; *d*, base pairing between the single-stranded 3' ends of the two homologues; *e*, DNA ligase seals the nicks, and the sequence-specific endonuclease makes new nicks (arrows); *f*, unpairing; *g*, DNA polymerase completes the molecule using the newly exposed 3' ends as primers. Note that in contrast to the mechanism in Fig. 1, the new strand contains no old DNA. Instead an exchange of old DNA has occurred between the two daughters.

direct or indirect attachments between the telomeres of nonhomologous chromosomes¹⁸ lends some support to this idea.

At leptotene of meiotic prophase in many organisms, all the telomeres become gathered together and attached to a small area of the nuclear envelope, presumably so as to facilitate pairing during zygotene^{16,21,23}. This characteristic polarised 'bouquet stage' persists until pachytene when pairing is complete. This phenomenon strongly indicates that all telomeres possess some common structural feature, which might simply be a common palindromic sequence, which could serve not only for replication but for recognition by the apparatus that brings the ends together.

Dupraw¹⁸ has instanced several cases where many or all of the mitotic chromosomes are attached to each other by fine connectives. He even goes so far as to suggest that all the chromosomes of a eukaryote haploid set are simply parts of a single continuous circular DNA molecule, as in bacteria. If this were true it would make the replication mechanism postulated here totally unnecessary. However, Dupraw's model raises more problems than it solves. For example, he fails to discuss the difficult problem of how two haploid super chromosomes could be integrated to make a single diploid circle.

He does recognise, however, that this extreme model can only be compatible with the genetic evidence for the independent assortment of linkage groups if the postulated 'DNA connectives' between the nonhomologous chromosomes are unusually 'labile'. His explanation of this is that the connectives contain no functional genes and that the lability is caused by normal recombination. This would imply, however, that very large amounts of DNA contain no genes but simply serve to connect the chromosomes together. In maize and *Drosophila* such nonfunctional interchromosomal connectives would have to amount to 60% and 75% of the lengths of the functional part of the chromosomes, respectively, if they are to give a recombination frequency of 50%. The need to postulate such huge segments of nonfunctional DNA, whose sole function is to join nonhomologous chromosomes together in such a way as to allow independent assortment, can be totally avoided by supposing instead that the observed linkages are purely temporary and that their lability is not the result of normal genetic recombination.

Indeed, if as suggested here, the ends of all chromosomes have identical sequences, which are sometimes single-stranded, one might expect nonhomologous chromosomes on occasion to join together by base pairing between these cohesive ends. If this did occur, and if DNA ligase were to join the chromosomes covalently, the specific endonuclease would ensure that this joining was not permanent. In principle the chromosomes could associate reversibly into a single superchromosome as indicated in Fig. 4*a*. Though this kind of mechanism could explain some examples of chromosome association, others involve association between regions other than the telomere, and could be explained in this way only if it were assumed that the DNA ends are not at the telomere.

I am grateful to the referee of this paper for drawing my attention to a paper by White²², who suggested that the occurrence of multivalents of terminally associated chromosomes in the meiosis of F_1 hybrids (and other situations where normal pairing is reduced) could be caused by minute regions of homology at the tips of nonhomologous chromosomes, and not by reciprocal translocation as had hitherto been believed. This hypothesis of reduplicated telomere regions was supported by Callan, who in a footnote to White's paper said "all new telomeres are probably homologous". Despite criticisms¹⁹ it remains a reasonable interpretation of at least some of the data, which is fully consistent with my assumption that all telomeres in any one species are homologous.

Fig. 4 *a*, The reversible formation of superchromosomes or, reading from right to left, an hypothesis for the origin of several linear eukaryote chromosomes from a single circular prokaryote chromosome (the 3' end of a polynucleotide shown by arrow, newly synthesised DNA by a thin line). *b-d*, Mechanism for the formation of minichromosomes during chromosome diminution or hypotrich ciliate macronuclear formation; *b*, the small arrows show the sites at which a specific endonuclease makes nicks at each end of special internal palindromic sequences; these sequences differ from the palindromic sequences at the original ends of the chromosomes. *c*, The nicks are made and, *d*, a DNA polymerase extends each newly formed 3'OH end, forming complete palindromic sequences at the new ends, and causing the new mini chromosomes to separate.

White pointed out that if many or most chromosomes have homologous telomeres, multivalent formation must normally be suppressed during meiosis. He suggests, however, that the homologies have no great evolutionary importance and originate quite fortuitously (though very commonly) by the reciprocal translocation of extremely minute segments, and the survival of resulting deficiency-duplication homozygotes. If the homologies are mere accidents, there is no obvious reason why the evolution of a general mechanism to suppress multivalents should have been selectively favoured over the simple alternative of eliminating the unnecessary duplications. By contrast, my suggestion that telomeres consist of identical palindromic sequences, with an indispensable role in replication, provides a strong selective advantage for the suppression of multivalent formation.

Chromatin diminution

In eukaryotes there are at least two instances where normal chromosomes are cleaved into smaller linear pieces or 'minichromosomes' which are subsequently replicated; these are chromatin diminution in the somatic cells of the worm *Ascaris* and other animals²³, and macronuclear formation in the ciliates *Stylonychia* and *Euplotes*^{24,25}. The replication of these 'new ends' will present exactly the same problems as that of the original ends of the normal chromosomes. I suggest, therefore, that these new ends must also consist of palindromic sequences, and that they are replicated in essentially the same way as the normal telomeres. Moreover, the site specific nuclease which functions in the replication of minichromosomes could be the same enzyme as the one which initially cuts the chromosome into minichromosomes, as both have to cut at the same site in the sequence. The only difference is that in replication only one strand is cut (Fig. 2e) whereas in making minichromosomes two staggered cuts are needed on opposite strands

(Fig. 4b). Two single-stranded ends will be produced and when the other strand is completed by DNA polymerase each minichromosome will have a complete palindromic end. To ensure that this cleavage does not occur in the germ line of *Ascaris* and in the micronuclei of the ciliate I suggest that the palindromic sequence and the endonuclease involved are different from those at the normal chromosome ends, and that the synthesis of the endonuclease is normally repressed and has to be derepressed to initiate chromatin elimination. This special endonuclease and palindromic sequence may have evolved from the normal ones involved in telomere replication.

Origin of eukaryote chromosomes

A necessary and crucial step in the evolution of a group of linear eukaryote chromosomes from a single circular bacterial chromosome must have been the evolution of some special mechanism for the replication of the chromosome ends. Unless this mechanism was present right at the outset, pieces would have been lost from the ends of the chromosome at each replication. Therefore I suggest not only that the palindromic telomere mechanism evolved from a bacterial restriction mechanism, but that this change was all that was needed to convert a circular chromosome into several linear ones. Thus Fig. 4a if read from right to left could be taken to represent the origin of separate eukaryote chromosomes.

It should be possible to test all the predictions of my model as methods for sequencing DNA and for isolating and working with unbroken eukaryote DNA improve.

Note added in proof: Work recently published by Wilson and Thomas (*J. molec. Biol.*, **84**, 115-144 (1974)) reveals numerous nearly perfect palindromes in eukaryote DNA, but does not indicate whether any are terminally located as my model would predict.

X-ray observations of the Coma and Virgo clusters from Copernicus

THE X-ray sources in both the Virgo and Coma clusters of galaxies are known to be extended. We report here observations to determine the spatial characteristics of each source using the two grazing incidence reflecting telescopes and the collimated proportional counters on board Copernicus¹.

The observations were made on January 6 and 7, 1973, and January 26 and 27, 1973, for the Virgo and Coma clusters respectively. In both cases only the widest field of view on the X-ray telescopes was used (effective beam diameter about 12') to observe seven regions, one centred on the source, and six spaced equally 10' from the centre position. The two telescopes covered the energy ranges 1.5 to 4.6 keV (3 to 8 Å) and 0.48 to 1.45 keV (6 to 18 Å) and the collimated counters the range 2.5 to 7.5 keV. A total of 254.7 min of usable data was acquired from the Virgo cluster and 382.6 min from the Coma cluster; the total observation time was approximately equally divided between the seven observing regions.

Coma cluster: It is now well established that the Coma cluster is an extended X-ray source²⁻⁵. The Uhuru results³⁻⁵ were originally analysed in terms of a uniform emitting disk, with a resulting diameter of $36' \pm 4'$ (ref. 5). A reanalysis of the data⁴ by Lea *et al.*⁶ in terms of more realistic models, including an isothermal gas sphere, resulted in smaller source dimensions. For the isothermal sphere models Lea *et al.* deduced a best-fit core radius $a = 16' \pm 3'$, and for a model in which the gas density $\rho \propto r^{-2}$ (the asymptotic approach to an isothermal sphere) they obtained $a = 7' \pm 2'$. Models for which the emission is proportional to the first power of the density, predicted for some nonthermal mechanisms, were excluded by their analysis.

The Uhuru observations could not distinguish between thermal or power-law X-ray spectra, but the low energy results from the rocket flight of Gorenstein *et al.*⁷ show that the spectrum is best fitted by thin source bremsstrahlung with $kT = 8.1 \pm 1.5$ keV (including an energy-dependent Gaunt factor), taking into account the absorption of 2.10^{20} hydrogen atoms cm^{-2} along the line of sight to Coma. A power-law spectrum appears to be excluded by the need for a hydrogen column density lying outside the acceptable range 1.5 to 2.5×10^{20} hydrogen atoms cm^{-2} (for the galactic latitude of Coma).

The X-ray telescopes on Copernicus observed a central region of Coma and six adjacent regions with 12' effective diameter⁸. A total of 63 min observing time was spent on the central region, which contains the cluster kinematic centre, the Uhuru X-ray centroid and the two prominent galaxies NGC4874 and NGC4869. In the 0.48 to 1.45 keV range, the 2σ upper limit on the flux from the central region corresponds to 1.3×10^{-2} photons $\text{cm}^{-2} \text{s}^{-1}$, and in the 1.5 to 4.6 keV band the recorded count, at 3σ above background, corresponds to a flux of 9.4×10^{-3} photons $\text{cm}^{-2} \text{s}^{-1}$, assuming the spectrum described here. In the outer regions, the average signal over the six bins gave 3.3×10^{-3} photons $\text{cm}^{-2} \text{s}^{-1}$ in the higher energy band (a 2.7σ result).

We have compared these observations with the counts predicted by spectral fits to the combined data from Uhuru and Gorenstein *et al.*⁶:

$$dN/dE = (0.044/E) G e^{-E/kT} \text{ photons cm}^{-2} \text{s}^{-1} \text{keV}^{-1}$$

where the Gaunt factor $G = 0.8 (E/kT)^{-0.4} E/kT > 0.1$
and $G = 1 - \log_{10} (E/kT) E/kT < 0.1$
with $kT = 8.1 \pm 1.5$ keV.

For the efficiencies of the telescope system covering the 0.48 to 1.45 keV band, the predicted count from the whole cluster is 375 ± 41 . The 2σ upper limit from the central bin was 54 counts and we can therefore state with 95% confidence that less than 14% of the total emission comes from the central 12' for this energy interval. For the higher energy band (1.5 to 4.6 keV) the predicted count from the whole cluster is 287_{-15}^{+17} . The observed count after background subtraction was 57 ± 27 (at 3.2σ above the mean background level, or $20 \pm 10\%$ of the predicted total).

Assuming an isothermal gas distribution $\rho = \rho_0 (1 + r^2/a^2)^{-3/2}$, the above result leads to a lower limit of $19.5'$ for the core radius in the 0.48 to 1.45 keV band, and a value $a = 15_{-3}^{+7}$ from the higher energy band. The positive error on the latter result is reduced by noting the ratio between the counts in the outer and central bins, giving finally $a = 15' \pm 3'$. This agrees well with the value $a = 16' \pm 3'$ from Lea *et al.*⁶ for a similar energy interval.

Following Lea *et al.* we have also fitted the density function $\rho = \rho_0 (1 + r^2/a^2)^{-1}$, or emission $\epsilon \propto (1 + r^2/a^2)^{-2}$, approached asymptotically by an isothermal sphere. For this function, the upper limit for a becomes $10'$ in the low energy band, and $a = 8' \pm 2'$ for the higher energy band, the latter measurement again agreeing with $a = 7' \pm 2'$ from ref. 6.

As a test on the reliability of the Copernicus results quoted here, we have compared them with predictions based on the Uhuru and Gorenstein results. The count observed in the 2.5 to 7.5 keV detector, which viewed the whole cluster throughout the observations was $2,873 \pm 192$ counts at 19σ above background. The total predicted count was $2,716 \pm 275$, the agreement to 5% accuracy being well inside the statistical uncertainties involved.

Thermal models for the origin of the Coma cluster X-ray emission are presently divided between those which invoke accretion for the origin of the gas⁹⁻¹¹ and those which explain the intracluster gas as a wind emanating from the cluster centre¹² with the energy coming from violent activity (see ref. 13), or by frictional heating. The inverse Compton models^{14,15} seem to be ruled out by the thermal shape of the X-ray spectrum, supported by the present observations, as well as by difficulties with the emission mechanism itself when applied to Coma^{16,17}.

The temperature distribution in the gas both for the accretion models and the wind models (heating by mechanisms inside galaxies, and by friction) is predicted to fall with angular distance from the cluster centre. The tentative results obtained in the present observations clearly show this trend, whilst not allowing a preference among these individual thermal models to be firmly stated. But the 'heating inside galaxies' model of Yahil and Ostriker¹² is given some support as the dominant mechanism, since the core radii found here agree well with those predicted.

Virgo cluster: Several rocket flights have observed a source at 1 to 10 keV in the direction of M87 and the Virgo cluster, as summarised by Lampton *et al.*¹⁸ for flights before 1971. Since then, the Lockheed Group have observed the

source between 0.2 and 1.6 keV (ref. 19) and found it to consist of a point source within a few arc mins of M87 and an extended source with its centroid displaced $\sim 0.2^\circ$ in the direction of the optical jet. The point source was found to contain $60 \pm 30\%$ of the total low-energy X-ray emission; the Uhuru data are consistent with up to 35% of the emission coming from a point source.

The best fit to the Uhuru spectral data²⁰ is a power law, supposedly arising from the inverse Compton effect. Extrapolation of this spectrum to lower energies, combined with the spectral points of R.C. Catura *et al.* (unpublished results consistent with the upper limits of Gorenstein *et al.*²¹) leads to a necessity for ageing of the electrons in the ambient photon field; self absorption, suggested by Kellogg *et al.*²⁰, is ruled out by the spectral data of R. C. Catura *et al.* (unpublished). Alternatively both sets of data are consistent with a thermal bremsstrahlung from a plasma at 36×10^6 K, with only 1.5×10^{20} hydrogen atoms cm^{-2} along the line of sight, consistent with radio observations in this direction.

A reanalysis by Ricketts²² of previous Leicester rocket flights which observed M87 shows agreement with the above bremsstrahlung spectrum in temperature and normalisation, without strong evidence for any variability (see also ref. 18). Uhuru observed no variability greater than 30% between observations four months apart²⁰.

As with Coma, the Copernicus telescopes were pointed at a central bin and six neighbouring regions of the Virgo cluster, where the central bin contained M87. The counts obtained were compared with those predicted from the thermal spectrum above:

$$dN/dE = 0.31/E \exp(-E/3.1) \exp(-\sigma N_H) \text{ photons cm}^{-2}\text{s}^{-1}\text{keV}^{-1} \text{ with } N_H = 2.5 \times 10^{20} \text{ hydrogen atoms cm}^{-2}.$$

In the 0.48 to 1.45 keV band we observed 71 ± 21 counts in 63 min of observation on the central bin (a signal 4.1σ above background), compared with $1,032 \pm 62$ counts predicted from the whole cluster; only $7 \pm 2\%$ of the predicted count was in the central bin. In the 1.5 to 4.6 keV band, we can set an upper limit of 10% of the predicted total cluster emission being in the central region containing M87 and the jet. These percentages are clearly inconsistent with the $\sim 60\%$ found by Catura *et al.*, and are well below the 35% upper limit set by Uhuru.

Assuming the isothermal gas distribution $\rho = \rho_0 (1 + r^2/a^2)^{-3/2}$, our results imply a core radius $a > 23'$ for the 1.5 to 4.6 keV band, and $a = 28' \pm 4'$ for the 0.48 to 1.45 keV band. Lea *et al.*⁶ found $a = 25' \pm 4'$ for the 2 to 6 keV range.

In the 2.5 to 7.5 keV detector with a wide field of view, the total observed count was $1,934 \pm 153$, compared with $1,711 \pm 174$ from the Lockheed/Uhuru spectrum quoted above. So our observed flux is consistent with Uhuru to an accuracy of $\approx 10\%$. We therefore infer that the total X-ray flux from the Virgo cluster in this energy range did not change by more than 10% between early 1971 and January 1973.

The OAO Copernicus observations of the Coma and Virgo clusters are consistent with the high-temperature isothermal gas sphere models already proposed for the emission, with some indication that the low-energy X-ray emission is more extended, as hypothesised for the Perseus cluster²³. There is no strong galactic X-ray source at the centre of either cluster, in contrast to the bright X-ray emitting Seyfert galaxy NGC 1275 at the centre of the Perseus cluster²³. We note that all three clusters contain active galaxies (strong radio sources) near their centres, but only Perseus has a strong infrared emitting Seyfert galaxy.

The absence of a strong point source in the Virgo cluster is in disagreement with Lockheed rocket flight data. We do find good agreement, however, with Uhuru data from the whole cluster (including M87) in the 2.5 to 7.5 keV range.

Prediction of radio structure in the two largest redshift QSOs

THE discovery that the optical objects identified with OH471 (0642+449) and OQ172 (1442+101) are QSOs with redshifts of 3.40 (ref. 1) and 3.53 (ref. 2), respectively, has stimulated considerable interest in their optical^{3,4} and radio properties⁵.

Here we present predicted angular sizes for the radio sources based on incoherent electron synchrotron emission. Such angular sizes, combined with a cosmological interpretation of the redshifts, determine the minimum variability timescales consistent with the absence of relativistic effects.

Figure 1 shows the radio spectral data of OH471 and OQ172 (ref. 5) and decompositions of the spectra into canonical self-absorbed synchrotron components. We have used the minimum number of canonical components consistent with the data and have made the simplifying assumption that all components of a given source have the same spectral index, α . Uncertainties in the data preclude a meaningful determination of the spectrum at the highest radio frequencies.

Table 1 lists the resulting properties of each component. The frequency ν_n and the spectral flux $F\nu_n$ connote the intersection of the extrapolated opaque and transparent portions of the spectrum of each component. The $\nu_n = 6.5$ GHz and the $\nu_n = 18.4$ GHz components of OH471 are not very well established, but any combination of canonical components in this frequency range results in similar angular sizes.

Table 1 Theoretically expected angular radii and timescales

Source		OH471 (0642+449)		OQ172 (1442+101)	
z		3.40		3.53	
ν_n [GHz]	0.84	6.5	18.4	0.26	0.94

$t_v(F_V^c = F_V^s)$ [yr]	90 (250)	6 (18)	3 (8)	150 (400)	50 (130)
t_v^{-1} [% per yr]	1.1 (0.4)	15 (5)	30 (12)	0.7 (0.24)	2.1 (0.8)
$B(u_e = u_m)$ [mgau]	15 (12)	130 (100)	300 (260)	6 (5)	19 (15)
$U(u_e = u_m)$ [$M_\odot c^2$]	50 (600)	1 (20)	1 (15)	100 (1000)	30 (300)

*Two values appear for each parameter dependent upon the cosmological model: They are calculated for standard Friedmann cosmologies with $q=1$ and with $q=0$ (in parentheses).

†The luminosity distance is based upon $(c/H)=6$ Gpc ($H=50$ km/s Mpc) ($H=50$ km/s Mpc) $^{-1}$.

The angular size of a compact nonthermal source depends only weakly on assumptions about physical properties or distance, if the radiation is incoherent electron synchrotron emission with no relativistic bulk motions¹¹⁻¹³. Angular sizes and assumed distances therefore imply a minimum timescale of variability in the absence of highly relativistic effects^{14,15}.

1 Jy = 1 f.u.

Estimation of the angular size of a compact radio source with known spectral form rests upon the establishment of its maximum brightness temperature. Compact nonthermal radio sources show a rather narrow range of maximum brightness temperatures, 10^{11} K $< T_n < 10^{12}$ K (refs 6, 7). Although this results partly from observational selection, it also follows as a direct consequence of synchrotron theory^{6,7}. For a given radio

spectrum, the small dispersion in brightness temperature allows an accurate estimate of angular radius θ , since $\theta(\nu_n, F_{\nu_n}) \propto T_n^{-1/2}$. Table 1, which lists angular radii calculated according to assumed values of four different physical source parameters, demonstrates the insensitivity of the angular radius (brightness temperature) to physical conditions in a source. The parameter (F_V^c/F_V^s) represents the ratio of spectral flux in Compton-scattered synchrotron photons to (extrapolated) synchrotron spectral flux. The other three ratios involve the energy densities in relativistic electrons (u_e), magnetic field (u_m), and radiation (u_r).

The insensitivity of θ to each of these parameters follows from readily derivable relationships (see Table 4, ref. 8):

$$\theta(F_V^c/F_V^s) \propto (F_V^c/F_V^s)^{-1/(2(3+2\alpha))} (1+z)^{(2+\alpha)/(3+\alpha)}, \quad (1)$$

$$\theta(u_r/u_m) \propto (u_r/u_m)^{-1/10} (1+z)^{3/5}, \quad (2)$$

$$\theta(u_e/u_m) \propto (u_e/u_m)^{-1/17} (1+z)^{9/17} D_1^{-1/17}, \quad (3)$$

$$\theta(u_e/u_r) \propto (u_e/u_r)^{-1/7} (1+z)^{3/7} D_1^{-1/7}, \quad (4)$$

with D_1 the luminosity distance. So even crude bounds to any of these ratios greatly restrict the angular sizes. In many cases, optical and X-ray observations require $(F_V^c/F_V^s) < 1$ (ref. 8) and the radio data alone generally suggest $(F_V^c/F_V^s) < 1$ (refs. 9, 10). If $u_r > u_m$, Compton energy losses dominate synchrotron losses; thus, to avoid catastrophic luminosities, $(u_r/u_m)^{1/10} \lesssim 1$. Although equipartition ($u_e = u_m$) seems unlikely in evolving compact sources and experience suggests $u_e > u_m$ (refs. 7, 8) it seems reasonable to expect that $(u_e/u_m)^{1/17} \approx 1$. Finally, (u_e/u_r) represents the weighted radiative lifetime of electrons normalized to the travel time of light across the source; consequently, in the absence of noncentral accelerations, $(u_e/u_r) \gtrsim 1$.

The canonical incoherent synchrotron model admits angular sizes smaller than those given in Table 1 only in the presence of relativistic bulk motions (for example, small pitch angles or relativistic expansion)^{8,9}. These minimum angular radii range in the lower frequency components between 2 and 6×10^{-3} arc s, and even the $\nu_n = 18.4$ GHz component of OH471 should have an angular radius in excess of 0.1×10^{-3} arc s. Very long baseline interferometric (VLBI) observations could confirm, therefore, the consistency of the canonical assumptions.

The source angular radius indicates a physical size

$$R = D_1 \theta (1+z)^{-2} \quad (5)$$

and, for variable sources, an index of variability

$$i_v = (R/c t_v) (1+z) \approx (D_1 \theta / c t_v) (1+z), \quad (6)$$

where the variability timescale $t_v = |d \ln F_V / dt|^{-1}$. In the absence of highly relativistic effects, $i_v \lesssim 3$ (ref. 9); conversely, for $i_v \lesssim 3$, there is a minimum t_v consistent with the assumed angular size and distance. Table 1 lists for each source com-

Fig. 1 Radio spectral data of: a, OH471 (0642+449); b, OQ172 (1442+101) from ref. 5. Points with no error bars have errors within the solid circles. Dashed curves represent best fit decompositions of those portions of the spectra indicated by solid lines into canonical self-absorbed synchrotron components.

ponent values of R and t_v , based on luminosity distances D_l calculated (assuming $c/H=6$ Gpc; $H=50$ km/(s Mpc)) for a Friedmann cosmological model with $q=1$ and for one with $q=0$. We note that for redshifts as large as three, the choice of cosmological model (q) significantly influences the allowed values of t_v and t_v^{-1} as well as some derived parameters such as the equipartition (minimum) energy content.

Present observations do not firmly establish the existence of variability in either of these sources, although Gearhart *et al.*⁵ suggest the possibility of a 20% decrease in OH471 at 1.4 GHz during a 4 yr span, as compared to a value $t_v^{-1} \lesssim 1\%$ per yr given in Table 1 for the relevant component. If such rapid variations are present, VLBI observations could ultimately decide among possible alternatives to the canonical assumptions made here^{8,9}.

We thank Dr J. Kraus and colleagues for sending us their data before publication and Drs G. R. Burbidge and W. A. Stein for discussions. This work is supported by the National Science Foundation and by NASA.

How long do radio galaxies emit at radio wavelengths

MANY clusters of galaxies from Abell's catalogue¹ have recently been observed at 1,400 MHz with the 300-foot radio telescope of the NRAO (ref. 2 and F. Owen, to be published). On the Palomar Sky Survey prints we inspected 355 clusters of galaxies (111 of them were observed by H.M.T.², the remaining 244 by F. Owen, to be published) which belong to distance group 5 and thus are situated at almost the same distance. Radio emission in excess of 0.1 flux units (f.u.) was detected from 95 out of the 355. A radio source was identified with a cluster of galaxies if it was within 5 arc min from the cluster centre, the diameter of which is about 25 arc min.

The study showed that:

(a) There are 27 clusters of galaxies in which the brightest is a cD-type galaxy (cluster type I according to Bautz and Morgan³). Eighteen of them emit at radio frequencies. Since the probability of detecting a radio source at the position of a cluster of galaxies is one in the case of observations of 22 clusters, if objects of both types are distributed randomly², the most probable number of

incorrect identifications is one or two.

(b) There are four clusters in which the brightest galaxy is a compact galaxy and two of them are radio emitters.

(c) Fifty-one clusters have two or three bright members, one of which is either a cD-type or a compact galaxy, or a peculiar galaxy, or a close double galaxy. Radio sources are found at the positions of 39 such clusters. Two or three of the detected sources may be located there by chance.

(d) There are 33 clusters in which a bright elliptical galaxy dominates. Radio emission is detected at the positions of only three clusters and two of these identifications could be by chance.

(e) There are 45 clusters which contain two or three bright E galaxies. Radio sources are found at the positions of six of them and two of these identifications are most probably spurious.

Since the angular resolution of the survey is greater than the diameters of the clusters it is possible to go one step further and check whether the dominant galaxy in the cluster is within the error box of a radio source position. In almost all the above cases this is so. Since radio sources are generally not resolved this means that radio emission originates in one galaxy of the cluster rather than in many members of it. Thus one can with great confidence identify the radio sources in the clusters considered with centrally located, bright cD compact, peculiar, close double or elliptical galaxies. The radio luminosities of these galaxies are of the same order as that of NGC4486 (Vigo A) and higher. The Hubble constant $H = 75$ km s⁻¹ Mpc⁻¹ and the mean redshifts of clusters of galaxies in distance group 5, given by Abell, were used to determine the radio luminosities.

(f) Most numerous are the clusters of galaxies which do not contain any one dominant galaxy or even 2 or 3 members sharply differing in brightness from the rest. In such clusters the differences in magnitude of bright member galaxies are small (cluster type III according to Bautz and Morgan³). There are 195 such clusters and radio emission is detected at the positions of only 27 of them. Moreover nine radio sources could be located at the positions of clusters purely by chance.

Thus, about 70% of clusters of the first three groups have radio emission associated with them and hence the bright galaxies of these clusters, which are either cD-type, compact, peculiar or close double galaxies, emit at radio wavelengths during at least two-thirds of their lives, or more precisely during the interval of time when they look like galaxies of the named optical types. The duration of the radio emitting phase may be even longer if not all such galaxies pass through this phase.

In clusters of galaxies of groups d, e and f, where the dominating bright member is of type E or there is no outstandingly bright galaxy, the occurrence of radio emission is seven or eight times less frequent than in clusters of the first three groups. Consequently these galaxies emit radio waves for not less than 10% of their lives.

We thank Mr F. Owen for making available the results of his observations before publication. We also thank Professor V. A. Ambartsumian for his interest in this project and for valuable discussions.

H₂O, O₃, N₂O and HNO₃ in the arctic stratosphere

MEASUREMENTS of the total amounts and average mixing ratios of a number of stratospheric trace gases at altitudes above 15 km have previously been published¹⁻³. The measurements were derived from submillimetre wavelength emission spectra, recorded on board Concorde 002 during high altitude test flights.

Here we report the preliminary results of further measurements from this aircraft, using an improved experimental system which permitted us to carry out a limb-scanning experiment to deduce not only the total amounts but also the vertical profiles of several gases.

The results were obtained during flights made in May 1973 into the Arctic circle. Prestwick international airport was used as an operations centre, and flights took place during both day and night, reaching a most northerly latitude of 72.5°N. The flight paths were generally triangular, with a rather short northernmost east-west or west-east leg. The present data were obtained on flights on May 16 and 16/17 (night), 1973. Flight altitude was a constant 50,200 feet (15.25 km). Take-off times were 1500 GMT and 2400 GMT. The results reported here were obtained between 65 and 70°N.

The interferograms were recorded once per 8 min, up to an optical path difference equivalent to 0.04 cm⁻¹. These were later Fourier transformed at the National Physical Laboratory (NPL). The atmospheric temperature profiles were obtained from the meteorological sounding network, with kind cooperation from the Meteorological Office. The analysis and spectroscopic assignments of the spectra have been described elsewhere^{1,2,4}. The method used for analysing the concentration profile was a standard limb-scanning method^{5,6}.

Figure 1 shows the initial results obtained, using spectral data from May 16/17, 1973. The diagram shows mixing ratio profiles for H₂O, O₃, HNO₃ and N₂O, a tentative column density for NO₂ and an estimated upper limit for SO₂; it also shows the volume mixing ratios evaluated for each species below 15 km. It is not possible to deduce unambiguously a mixing ratio distribution profile above the flight altitude and so we have quoted only the total

Fig. 1 The vertical distributions of H₂O, O₃, N₂O and HNO₃, at 65–70°N, measured in the limb-scanning experiment on Concorde 002, May 1973, from an altitude of 15 km. Below 15 km, concentrations are quoted explicitly in volume mixing ratio units; above 15 km, total column number densities (cm⁻²) are quoted at the top of each curve. The curve above 15 km represents the (assumed constant) volume mixing ratio equivalent to the quoted column density. At the top left the range of column densities observed for NO₂ is given, and an upper limit to the amount of SO₂.

Fig. 2 Results of the inversion procedure for N₂O (May 16/17 at 65–70°N). The stepped curve shows the present results; broken curve, our previous results²; solid curve, some recent results by Murcray *et al.*¹²; bar-dash curve, results by Schutz *et al.*¹³; dotted curve, some earlier results by Murcray *et al.*¹⁴.

column number density above this level. These are the numbers shown at the top of each curve; the values range from 10¹⁹ molecules cm⁻² to less than 10¹⁵ molecules cm⁻². This range of column density may be obtained from a single spectrum, demonstrating the power and dynamic range of radiative methods such as ours. The broken lines with arrows represent the equivalent effective mixing ratios, if constant mixing is assumed, and are shown for comparison.

The shaded areas at the left are for NO₂ and SO₂. In the case of NO₂ we have measured the Q branch at 37.78 cm⁻¹; this, unfortunately, does not yield any information below the horizon, because nearby strong H₂O lines become so intense that the NO₂ Q branch is 'obscured'. Thus information on the column density only has been obtained. The box shown represents the range of values of column number density observed, 0.5 to 1.3 × 10¹⁶ cm⁻² converted to an effective average volume mixing ratio (see above). Some limited evidence is available of a variation between day and night, but more evidence is necessary before it can be regarded as conclusive. In the case of SO₂ there is still uncertainty in our assignments and, moreover, in the value of integrated line strength which should be used. The box thus indicates that we can place an upper limit on the amount of SO₂ above 15 km of 2.6 × 10¹⁵ cm⁻², corresponding to an effective average volume mixing ratio of 1 × 10⁻⁹. This is not an absolute measurement and the true value could be much lower than this.

Below 15 km, we give mixing ratio profiles for H₂O, O₃, HNO₃ and N₂O. The results are given as the average volume mixing ratio in 1.5 km thick layers.

For water vapour, the mixing ratio drops from a value of about 4 × 10⁻⁶–5 × 10⁻⁶ at the tropopause to about 3 × 10⁻⁶ at 15 km and seems to stay near this value above 15 km. We have previously obtained a large amount of information in this region of the stratosphere on the humidity distribution and have invariably found similar behaviour (see Fig. 2 of ref. 1). No diurnal variation was observed.

The ozone profile yields a total amount in good agreement with the limited meteorological network data that were available³ and indicates fairly high mixing ratios in the 11–15 km layer, as might be expected for polar spring maximum

conditions. We are at present analysing similar data taken in October 1973 and hope to compare the spring and autumn profiles. A variation in the amount of ozone between the day and the night flights was observed, which agrees fairly well with meteorological data.

The N_2O profile is basically a constant mixing result, with some indication of a falloff above 15 km. The average mixing ratio in the lower stratosphere is, however, approximately 300×10^{-9} , somewhat higher than the accepted value of 250×10^{-9} . The N_2O results have been replotted in Fig. 2 on a linear scale of mixing ratio and the results of several other workers are shown for comparison. C. B. Farmer and R. A. Toth (private communication) report results similar to Murcray's and our own.

Thus there still seems to be uncertainty about the N_2O profile in the lower stratosphere and it is an open question whether the observed variabilities are a consequence of real atmospheric variations or instrumental effects. It is not possible in the present work to obtain any information about N_2O above about 17–18 km. We did not detect any diurnal effects.

Finally in Fig. 1 we consider the mixing ratio profile obtained for HNO_3 . The mixing ratios seem slightly but significantly higher than those given by Murcray^{8,9} for the same levels but obtained at lower latitudes. Murcray does, however, report higher concentrations in results he has obtained over Alaska at similar latitudes to our own¹⁰ and what is observed may be an effect based on tropopause height and seasonal variations, similar to that found for O_3 . No diurnal variation was detected.

Figure 3 shows the HNO_3 data replotted on a linear mixing ratio scale and compared with other results (the column density above 15 km has been arbitrarily contained below

Fig. 3 The results for HNO_3 (May 16/17, 65–70°N) compared with previous measurements. The broken curve is by Murcray *et al.*⁸ as are the squared points⁹; the light triangle and quadrangle enclose points measured by Lazarus *et al.*¹¹. Total column density (10km–top) = 3.14×10^{-4} cm atm.

25 km in order to simulate a layer for the purposes of the diagram. See Fig. 1 for the corresponding column density.) The broken curve is a result by Murcray's group in mid-latitudes⁸, the squares represent the extreme values of a "double-layer" observed by the same group⁹ and the two areas enclosed by polygons circumscribe the range of values obtained, again in mid-latitudes, by Lazarus and coworkers¹¹.

We are at present analysing data for October 1973 and we hope to compare spring and autumn results for HNO_3 in this way.

The picture emerging for HNO_3 seems to be reasonably consistent between the various groups of workers, although at the moment unexplained variations in the total amount do occur, ranging over about a factor of 2. The mean pressure column density seems from our work to be about 2.5×10^{-4} cm atm (in agreement with Murcray *et al.*).

The results reported here are some of the first to be obtained in the Arctic stratosphere, an important part of the atmosphere *vis-à-vis* stratospheric contamination by aircraft because of the typically low tropopause, which means that transpolar and North Atlantic flights spend a large fraction of their time well above the tropopause. They are also the first results from a submillimetre wave limb-scanning experiment.

We thank the following for their help and cooperation: at the NPL, Dr N. W. B. Stone, Mr K. H. Hursey and Mr W. Clutterbuck; at the British Aircraft Corporation, Mr. B. Trubshaw and his many colleagues at Fairford, and Mr J. Leach and his colleagues at Bristol; the British Oxygen Company; and the management of Prestwick Airport.

'Cold spot' in West Africa: anchoring the African plate

VERY low heat flow values of $18 \pm 2 \text{ mW m}^{-2}$ ($0.42 \pm 0.04 \text{ } \mu\text{calorie cm}^{-2} \text{ s}^{-1}$) and $22 \pm 2 \text{ mW m}^{-2}$ ($0.51 \pm 0.05 \text{ } \mu\text{calorie cm}^{-2} \text{ s}^{-1}$) have been determined for two sites 85 km apart on the West African Precambrian shield in the Niger Republic (Table 1).

Temperature surveys were carried out with a thermistor probe in March 1972 in three boreholes, 245 m, 406 m, and 315 m deep, respectively, in western Niger. The thermal

conductivities of solid rock disks, saturated with water before measurement, were subsequently determined on a conventional divided bar apparatus.

Figure 1 shows temperature profiles with depth, temperature gradients calculated for 20-m intervals, and thermal conductivities for the analysed portion of three holes. Two sets of temperature data are shown for site K15. Heat flows were calculated using both K15 gradients; the mean is recorded in Table 1 and agrees very well with the heat flow determined from the nearby site, K6B.

The increasing gradient with depth in K6B (Fig. 1) is puzzling in view of the apparently uniform conductivity of the samples from that hole, and suggests the possibility of recent climatic warming. The consensus of climatological opinion¹, however, is that the region was, if anything, cooling rather than warming during recent times. Furthermore, the Donkolo site does not confirm the speculation of a recent regional warming.

The results of radioactive heat production measurements on aggregate samples of core chips are given in Table 1. The mean of $1.2 \text{ } \mu\text{W m}^{-3}$ for the basement rock at the Kourki site is taken to be representative of the region.

The two sites of the heat flow determinations are both located in Precambrian terrain on the eastern edge of the exposed West African craton. Six K-Ar ages of rock within 100 km of the heat flow sites² range from 2,487–1,206 Myr. The heat flow values reported here substantiate the general observation of low heat flow in Precambrian shields, a result anticipated by Beck and Mustonen³ from temperature measurements in boreholes in Ghana. These west Niger heat flow values are, however, considerably less than the mean heat flows of any of the other shields. The Southern Africa craton provides a useful comparison; there, fifteen measurements range from 36 to 59 mW m^{-2} with an average of 49 mW m^{-2} . The worldwide average of all shields is near 40 mW m^{-2} .

When heat flow data are coupled with information about the distribution of radioactive heat sources, reasonable estimates of temperatures at depth can be made. For a continental shield, Sclater and Francheteau⁴ outline a heat production model based on the petrological concepts of Ringwood⁵ and compatible with observed heat flow and surface heat production data. A surface heat flow in the Sclater-Francheteau model of 40 mW m^{-2} is comprised of 28 mW m^{-2} arising from radioactive heat sources in the outer 400 km of the Earth and 12 mW m^{-2} originating at greater depth.

It is clear that the Niger heat flow could be satisfied entirely by the flux originating above 400 km in the Sclater-Francheteau model, or with appropriate fractions of both the shallow and deeper flux. We reject the former option because it possibly implies a nearly isothermal lower mantle, a condition we think unlikely. Therefore, we have calculated temperature models that include some flux from below 400 km, consistent with two constraints: first, the measured surface heat flow, 20 mW m^{-2} ; and second a near surface radioactive heat source distribution that diminishes exponentially downward from the measured surface value of $1.2 \text{ } \mu\text{W m}^{-3}$. The logarithmic decrement of the near surface heat source function and the temperature dependence of the thermal conductivity remain variable parameters of the models.

Two temperature models for Niger, along with a typical 40 mW m^{-2} shield geotherm and a melting point curve, are shown in Fig. 2. One model, which we have called an 'upper limit' model, represents the likely upper limit for the temperature distribution beneath western Niger, consistent with the listed constraints. It is characterised by a logarithmic decrement of the heat source of $(5 \text{ km})^{-1}$ and a uniform thermal conductivity of $2.5 \text{ W m}^{-1} \text{ K}^{-1}$. We prefer the second model which uses a logarithmic decrement of $(8 \text{ km})^{-1}$ and a modest increase of thermal conductivity

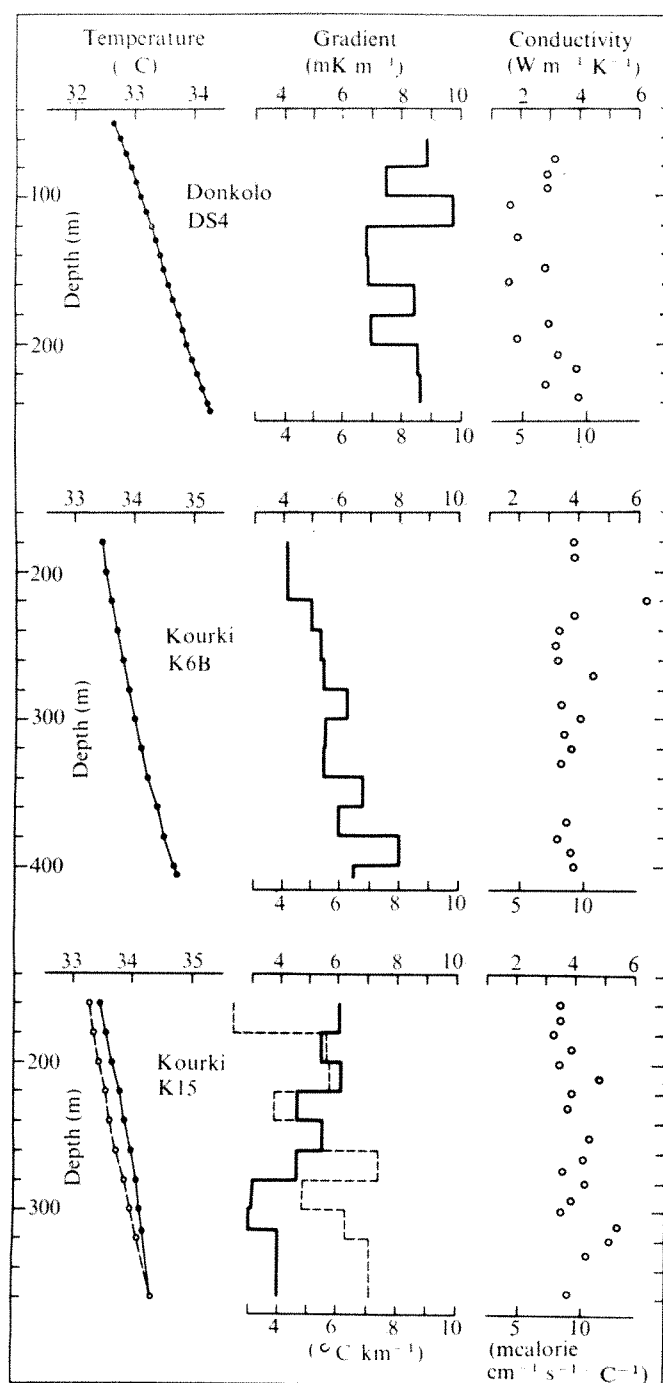

Fig. 1 Temperatures, gradients and conductivities for the analysed portions of the boreholes. In the graphs for K15 the solid curve represents a survey made nine days after drilling had stopped at 315 m, and the dashed line represents equilibrium temperatures predicted from two additional surveys made soon after the hole was deepened to 360 m. The nine-day curve and the predicted equilibrium curve bracket the measured equilibrium profile for K6B which was only 200 m away.

Table 1 Heat flow and heat production data

Site	Latitude	Longitude	Borehole	Depth interval (m)	Heat production ($\mu\text{W m}^{-2}$)	Heat flow (mW m^{-2})
Donkolo	14° 53'N	0° 55'E	DS4	60-245		18 (0.42)
			DS3	140-250	1.8 (4.3)*

* Numbers in brackets refer to heat production in 10^{-13} calorie $\text{cm}^{-3} \text{s}^{-1}$ and heat flow in $\mu\text{calorie cm}^{-2} \text{s}^{-1}$.

with temperature, following Schatz and Simmons⁶. Neither of the Niger models reaches the temperatures of the average shield geotherm. Furthermore, unless the entire section of the upper mantle below the West African shield is severely depleted in heat producing isotopes, the heat flow originating below a depth of 400 km must be only 7 mW m^{-2} , about half the corresponding value for the average shield. We therefore must conclude that the Precambrian crust and underlying upper mantle of western Niger probably comprise one of the coldest regions in the outer 400 km of the Earth.

The mechanical consequences of this 'cold spot' are worth brief consideration. The plate tectonic model of Earth dynamics envisions a rigid, mechanically strong lithosphere overlying a weak and deformable asthenosphere. The base of the lithosphere has no rigorous definition; it is commonly equated to the top of the upper mantle seismic low velocity zone. This zone usually begins at depths of 50-150 km, depending on the tectonic setting. We suggest another working definition for the boundary between the lithosphere and the asthenosphere: that depth at which the viscosity of the Earth has diminished from its high surface value to $10^{20} \text{ kg m}^{-1} \text{s}^{-1}$ (10^{21} poise). Such a viscosity for the asthenosphere is suggested by postglacial rebound, and also

by the velocities of lithospheric plate motion over the asthenosphere.

We have calculated the viscosity as a function of temperature, and thus of depth, for the temperature models shown in Fig. 2. We have followed the development of Weertman⁷, which relates the viscosity to temperature-dependent creep and dislocation glide. The calculations assume a stress of 10^4 N m^{-2} (0.1 bar) and the melting curve shown in Fig. 2. The calculated viscosity profiles also are shown in Fig. 2. The model for the average shield temperature implies a lithospheric thickness of some 175 km for a typical shield, a value quite consistent with seismically determined values reported for various shields. The two models for West Africa suggest that the lithosphere there extends to depths well below 400 km; whether an asthenosphere is developed at greater depths is somewhat uncertain. Our conclusion is that the lithosphere is very thick, and that the asthenosphere is very thin or absent beneath West Africa.

The logical consequence of a thick lithosphere and a poorly developed or absent asthenosphere would be that the motion of the lithosphere would be impeded. In the extreme, the plate would be rendered immobile. Burke and Wilson⁸ have indeed suggested that such has been the case for the African plate since the early Miocene.

Has the African plate run aground?

We thank the Government of the Niger Republic and Dr E. G. Schroeder, Project Manager of the United Nations Development Program for mineral exploration in Niger, whose cooperation and assistance made possible this research. Professor Robert F. Roy made the radiogenic heat production measurements. Financial support was provided by the Rackham School of Graduate Studies of The University of Michigan and the US National Science Foundation.

Magnetic behaviour of some partially unmixed titanomagnetites

THE remanent magnetisation of igneous rocks is mainly carried by titanomagnetites. To obtain reliable information about the Earth's field during the past it is necessary to understand the mechanisms involved in the acquisition of remanence and in any subsequent changes. Much information has been obtained by studying basalts, but this approach is limited because of unknown factors such as grain size, degree of subsequent oxidation and impurities present. Synthetic, sintered samples of known composition have been used by many workers in order to avoid these difficulties.

In our present work, sintered titanomagnetite, $\text{Fe}_{3-x}\text{Ti}_x\text{O}_4$ (with $x=0.5$, denoted TM50) was used to prepare simulated average basalt by dispersing a known quantity of a selected particle size into a silicate nonmagnetic matrix (powdered Pyrex or silica). This study was undertaken in order to investigate reversals of magnetisation observed in natural basalts¹. The simulated sample showed a partial reversal of remanence when cooled in zero field. The study was then extended to the compositions TM40 ($x=0.4$), and TM60 ($x=0.6$).

The samples were prepared by a double sintering procedure² at $1,350^\circ\text{C}$ in a sealed mullite tube filled with a mixture of CO_2 -CO which acted as an oxygen buffer and at the same time aided the oxygen transfer between Fe and Fe_2O_3 in the initial mixture consisting of Fe, Fe_2O_3 , and TiO_2 . All samples were cooled at approximately the same rate given by the normal cooling rate of a massive furnace. It took about 15 h for the furnace to cool from $1,350^\circ\text{C}$ to room temperature. The samples were chemically analysed (% of Fe^{2+} by wet chemical analyses, Fe:Ti ratio by electronprobe microanalyses) and their phase uniformity checked by X-ray analyses using Debye-Scherrer and Guinier-de Wolff cameras. All samples were nearly stoichiometric and free of stray phases. Initial susceptibility, and saturation magnetisation-temperature curve confirmed this. The size of individual crystallites (grains) in the densely sintered tablets ranged from about 20 to $160\text{ }\mu\text{m}$, grains of

$40\text{ }\mu\text{m}$ being most abundant.

A part of the TM50 material was powdered and fractionated into various particle sizes by means of a centrifugal dust classifier. But, in this study only the fraction containing particles from 20 to about $50\text{ }\mu\text{m}$ was used. It was mixed with specially dried powdered Pyrex to give 3.5% by volume of the titanomagnetite in the non-magnetic matrix. The mixture was enclosed in a Pyrex capsule. This was evacuated and outgassed and the capsule sealed off in such a way that the magnetic particles were immobilised.

The sample was given an isothermal remanent magnetisation (IRM) at room temperature in a direct field of 5 kOe. The result of continuous thermal demagnetisation in zero field obtained by means of an astatic magnetometer

Fig. 2 Magnetic remanence as a function of temperature for *a*, TM60, *b*, TM50, and *c*, TM40. *d*, TM50 annealed at $1,100^\circ\text{C}$. Heating curve (●), cooling curve (○). The values of remanence at 35°C are shown on the left vertical axis (reduced four times). The Curie temperatures determined from susceptibility measurements are indicated on the temperature axis as bold marks. Inset 1: Pyrex (quartz) capsule with TM40, 50, and 60; 1*a*, coarse particles of titanomagnetite; 1*b*, powdered Pyrex (quartz).

next to the heating furnace³ is shown in Fig. 1. The two Curie temperatures show that while the bulk of the material is TM50, magnetite is also present. The amount of magnetite proved to be under the detection range of X-ray analyses, while low field susceptibility and saturation magnetisation-temperature curves suggest a very small quantity of magnetite (possibly under 1% by weight). If the demagnetisation was stopped at about 280°C (after the Curie temperature of TM50 was reached) and the sample was then cooled in zero field the remanent magnetisation showed a partial reversal on cooling through the Curie point. The same result was observed after prolonged heating to higher temperatures.

To investigate further the partial reversal, samples of TM40, TM50 and TM60 were prepared in a time-saving way as indicated in the inset to Fig. 2. All the magnetic sample in the form of relatively large pieces broken off from the original tablet (ranging in size from about 0.1 to 1.0 mm) was confined to the bottom space of a Pyrex (or quartz) ampoule. The three samples were then given an IRM in a field of 5 kOe. The results of continuous thermal demagnetisation are shown in Fig. 2. The curves exhibit a sudden increase of remanence at the Curie temperature of each composition respectively and the final Curie temperature of magnetite. If the samples were cooled after the first Curie point had been reached and before total demagnetisation occurred, a very sharp decrease in remanence was observed at a slightly higher temperature than the 'jump' observed on heating. The coarsely crushed sample of TM50 was then annealed at $1,100^\circ\text{C}$ for 3 h in an attempt to resorb the small quantity of magnetite. To avoid any appre-

Fig. 1 Magnetic remanence as a function of temperature for simulated basalt. Heating curve (●), cooling curve (○). Inset 1: Pyrex capsule with the simulated basalt; 1*a*, layer of TM50 particles dispersed in powdered Pyrex; 1*b*, protective layer of powdered Pyrex.

ciable unmixing occurring on cooling, the sample was rapidly removed from the hot furnace into a water-cooled brass jacket. This was successful, as in the repeat demagnetisation experiment the strange behaviour in the vicinity of the Curie temperature of TM50 practically disappeared (Fig. 2 curve *d*). It is noteworthy that the initial value of IRM exhibited by the sample at room temperature (see point *d* on the left vertical axis in Fig. 2) was very much smaller than previously. All these results suggest the possibility of a strong coupling between the magnetite regions present and the original titanomagnetite matrix.

The partial reversal observed on cooling of our simulated basalt seems to be similar to partial reversals demonstrated in natural basalts^{1,4-6} and in synthetic TM60 (ref. 7). This effect has been explained by negative magnetostatic coupling between the original spinel and a partially-oxidised cation-deficient spinel with higher T_c . In our samples, however, oxidation was ruled out. So, this explanation cannot account for the features of the curves shown in Fig. 2. We believe that all our observations are related to the same phenomenon—the presence of segregated magnetite and the resulting coupling. Small regions of magnetite are most likely to be the product of subsolvus segregation (in petrological terminology usually called ‘unmixing’) from the originally homogeneous single phase titanomagnetite. The curve confining the miscibility gap in the magnetite–ulvöspinel solid solution series is reported to be of the simple ‘hoop-shaped’ type⁸. It is known, however, that the ‘two spinels’ field in the appropriate phase diagram⁸ is still rather tentatively marked and much less is known about the kinetics of unmixing. Nevertheless, the phase diagram shows that the critical temperature for unmixing for the three compositions studied here should lie between 500° and 700° C. Unmixing in our samples is therefore likely to have taken place during the relatively slow cooling after their final sintering.

The correlation between the position of the jump and the Curie temperatures is obvious. The temperatures marking the onset of the jump on the heating curves correspond approximately to 160°, 230°, and 315° C for TM60, 50, and 40 respectively. The corresponding Curie temperatures determined for the latter samples from the susceptibility-temperature curves were 159°, 227° and 320° C. The reproducibility of the curves in Fig. 2 shows that no unmixing is taking place during the thermal demagnetisation. The jump is also reversible on cooling except for a hysteresis which grows with increasing x value.

The magnetic behaviour of the samples in our experiments can be phenomenologically explained in the following way. Below the Curie point of the matrix its permeability is high and some of the magnetic lines of force emanating from the magnetite regions are trapped in the matrix of the parent titanomagnetite. This results in a reduced amount being sensed by the astatic magnetometer. On passing the Curie point the permeability of the matrix drops, so that the lines of force emanating from the magnetite inclusions spring out of the sample and the magnetometer records a sudden increase in moment. When the sample is cooled the permeability rises sharply at the Curie point of the matrix and the lines of force from the inclusions are once more partially trapped and the decrease in moment is produced. The onset of these downward jumps which occurs at slightly higher temperatures may indicate that the regions adjacent to the magnetite inclusions could be slightly richer in iron than the bulk of the matrix. Some other mechanism might account for these hystereses, however, such as temperature-dependent reordering of cations. Research into this possibility is under way. In fact, we have observed similar hystereses on the susceptibility-temperature curves.

The simulated rock does not show the relaxation on heating through the Curie point. This may be associated with the different history of this sample, in that the titanomagnetite particles are smaller, mutually separated by non-magnetic material and strained because of grinding. More experimental data are needed.

It seems that measurements of magnetic remanence provide a very sensitive method of studying the process of unmixing in titanomagnetites from the very initial stage. It may also prove valuable for studying the kinetics of unmixing. We believe that further research carried along these lines will have petrological as well as palaeomagnetic significance as the process of unmixing is undoubtedly very common in natural basalts.

This work is supported by the Natural Environment Research Council. We thank Professor K. M. Creer for encouragement and Dr A. Stephenson for valuable discussions, in particular for suggesting the permeability mechanisms of magnetic coupling the simplified form of which is presented in this communication. We thank the Research Division of the National Coal Board, Newcastle-upon-Tyne, for the use of their centrifugal dust classifier.

Humic substances from seawater

SINCE the first spectroscopic observation of humic substances in seawater¹, it has been presumed that they constitute a considerable fraction of the dissolved organic matter in the sea²⁻⁴. Base-soluble organics were first isolated from seawater in 1958 (ref. 5), but the chemical composition and source of these materials has remained speculative and controversial^{3,6-9}. We here present evidence that humic substances in the Sargasso Sea display bulk characteristics which differ from those of humics from coastal waters and especially from those of humic substances isolated from soils and marine sediments.

Water from the north-western Sargasso Sea (surface and 1,500 m), and coastal water off Woods Hole, Massachusetts, has been analysed. Batches of seawater (400 l each) were acidified (pH 2, HCl) and passed through Amberlite XAD-2 resin¹⁰. (The resin was cleaned prior to use by batch extraction in refluxing benzene until NH₄OH, ethanol, and methylene chloride concentrated eluents showed no ultraviolet absorption. An extraction efficiency of 95.2% was determined when isolated humic substances were redissolved and adsorbed on Amberlite XAD-2 from salt water (pH 2) at 1.7 bed volumes per minute.) Salt was eluted with distilled water and humic materials were eluted with NH₄OH (pH 11.6) and recovered by freeze-drying. The humic materials were further fractionated by dissolving the fulvic acid (FA) in 0.01N HCl and the humic acid (HA) in NH₄OH. Freeze-drying these fractions yielded FA:HA ratios of 97:3 (by weight) in Sargasso surface water, 78:22 in

Fig. 1 Latitude time plot of 5-d mean position of surface East Pacific high pressure cell for winter of 1973. D, J, F, and M are abbreviations for the months (December through March). The symbol R denotes rainier halves and D drier halves of successive 27-d intervals. The upper tick marks indicate days it actually rained in Los Angeles.

graph of the 5-d mean positions, plotted on the third day, of the principal centre, or cell, of highest pressure of the semipermanent East Pacific high pressure cell in the region 19 to 50°N and 120 to 165°W for the 1973 winter (Los Angeles is at 34°3'N and 118°14'W). On average, the cell was more southward during rainier halves and more northward during drier halves of the 27-d intervals. The oscillation seems to be greater and more regular in winter than in other seasons.

This rainfall cycle might be related to a cyclic latitudinal oscillation of the jet stream at west coast longitudes. This oscillation might, in turn, cause a cyclic latitudinal oscillation of the resident East Pacific high pressure cell. The oscillation might then modulate the rainfall. The oscillation's phase would then determine whether Pacific storms move inland and eastward across Northern California or whether the storms move southwards. The respective positions about which the jet stream and Pacific high cell oscillate move farther south¹ as the rain season progresses with greater effects on conditions in Southern California (population 12×10^6) as the season progresses.

Records of daily precipitation for 1921 to 1971 for Los Angeles, Santa Barbara (34°25'N, 119°42'W) and San Diego (32°43'N, 117°9'W) were obtained from the National Climatic Center, Asheville, North Carolina. Additional Los Angeles Civic Center data from 1900 to 1920 were obtained from the Los Angeles office of the National Weather Service. The mean annual rainfall for Santa Barbara is 17.63 inches compared with 14.42 inches for Los Angeles (Table 2) and 9.76 inches for San Diego. The lower frequency part of the power spectrum for each of these cities is plotted in Fig. 2. The time series used for each spectrum was the cube root of the daily rainfall²⁻⁴. The entire continuous record was used to make each power spectrum and the data were also detrended. The Blackman-Tukey

method⁵ and the Tukey spectral window were used to compute the power spectrum, with 250 lags (equal maximum lag number). Twice as many spectral estimates as lags were computed⁶. The spectral estimates are statistically correlated in a band but greater resolution is obtained.

The 80% confidence interval is used as the standard of significance⁶. For the five curves the heights of the peaks at 54 d and 27 d (and for the 13.5-d peak in most cases) are equal to or larger than the 80% confidence interval and are therefore considered to be significant. There is a significant peak at almost exactly 27.0 d. The frequency for that spectral estimate is 0.037 cycles d⁻¹ which gives

Fig. 2 Power spectra of Southern California rainfall records. The five superimposed curves, numbered 1 to 5 from top to bottom, give lower frequency part of power spectral density as a function of frequency. The left-side ordinate scale of 0.10 to 0.80 is for curve 5. The 0.10 level for each curve is shown on the right side. Curves 1, 2, and 3 represent, respectively, spectra of Santa Barbara, Los Angeles, and San Diego, for the interval December 1927 through 1971 and each have 129 degrees of freedom. Curves 4 and 5 are spectra for Los Angeles for years 1936-1971 and 1900-1935, respectively, and each have 105 degrees of freedom. The vertical bars at very top are 80% and 95% confidence intervals for curves 1, 2, and 3. Below them are confidence intervals for curves 4 and 5. The horizontal bar in upper left corner is spectral bandwidth. Arrows a, b, c and d, denote peaks at 365, 54, 27 and 13.5 d, respectively.

$1/0.037 = 27.03$ d. The spectra for Los Angeles in curves 4 and 5 were obtained for time intervals completely independent from each other. San Diego is 180 miles to the south-east of Santa Barbara. The 27-d and 54-d peaks at Santa Barbara meet the very stringent 95% confidence interval standard⁶. Santa Barbara is 80 miles west and 30 miles north of downtown Los Angeles and is closer to the central longitude of the semi-permanent, East Pacific high cell. Thus, the storm blocking capability of this cell may be more effective at Santa Barbara, producing relatively larger 27- and 54-d peaks there. This possibility suggests that the closer the cell's average longitudinal position is to the west coast, the more dominant is the 27-d rainfall cycle.

The curves suggest two sets of harmonically related bands. The harmonics of "Set A" are separated by 0.009 cycles d⁻¹ (fundamental period ~ 108 d). The harmonics of "Set B" are separated by 0.012 cycles d⁻¹ (fundamental 81 d). In

Table 2 Monthly rainfall, in inches, at downtown Los Angeles station, averaged over the years 1921 through 1971.

January	2.84	July	0.00
February	2.93	August	0.03
March	2.11	September	0.25
April	1.34	October	0.38
May	0.22	November	1.56
June	0.07	December	2.69

neithercase is the fundamental marked by a peak. The first apparent peak in Set A is at 54 d and in Set B it is at 27 d. The peaks at 27 d and 13.5 d are effectively common to both sets. There are no peaks at Set A harmonics at 0.056 cycles d^{-1} and 0.065 cycles d^{-1} . Curves 1, 2, and 3 contain a mixing of both sets. The Los Angeles spectrum for 1936–1971, curve 4, is dominated by Set A and that for 1900–1935, curve 5, contains more of Set B than curve 4. On curve 5 there are indications of contributions but no peak by the Set B fundamental at 0.012 cycles d^{-1} and by its first harmonic at 0.024 cycles d^{-1} . These contributions partially fill in regions that are troughs at those same locations on curve 4 and seem to shift the two nearby peaks to lower frequencies on curve 5.

The Los Angeles computer tape was used in simulating forecasts for the past 50 yr (Table 3). The oscillation of the Pacific high cell (Fig. 1) suggests the primacy of the 27-d cycle. The other two large significant peaks, at 54 d and 13.5 d, are related to the 27-d cycle by factors of 2. The forecast was simulated by finding the early trend in the

27 cycle days (using two 27-d periods) that revealed the pattern that might continue. The first day after September 23 with ≥ 0.26 inches of rain or ≥ 0.26 inches total in two adjacent days was taken as point 1. The area in the next 27-d period under point 1 (23 to 30 d later) was searched for nearby days on at least one of which there was ≥ 0.16 inches. If this condition was not met, then a second point was searched for. When the day with a repeating pattern was found, it was taken as the "centre" day of the 13.5 days in a rainier half cycle. Only rain in this half cycle in cycles (to June 30) after the ones used in the trend establishment was totalled, and the ratio to rain in the other half cycle was calculated and printed in column B. The summation of the rains for the ratio in column B was started on the first day of the first drier half in the cycles to be included. This day was the eighth day after the centre day of the second 27-d interval used in establishing the early trend. If there was no more than 0.25 inches on any day between September 24 and December 31, then no forecast was made (Next to column B and 0.0 in column B). In a real-time forecast in the early autumn, one must distinguish and eliminate the very infrequent local thunderstorms and Sonoras (storms from Baja, Mexico). The average for the ratio in column B is 2.40 and 31 yr, or 67.4%, exhibited a ratio of 1.10 or greater, the criterion used for "success". Most forecasts (58.7%) were started (column E) before January 1.

Climatological rainfall statistics for Los Angeles, based on 1919–1973, were available at UCLA. We have examined climatological daily averages and determined the positive skill score over climatology from the formula^{7,8} $(C-S)/(T-S)$, where C is the number of correct forecasts (ratio in column B ≥ 1.10), and T is the total number of forecasts made. S is the number of those correct forecasts in column B that were also correct when the climatology statistics were used in column C or D in place of actual rainfall. If we take 1.05 or above, instead of 1.10, as an indication of success in columns C and D, then $S=6$ for column D and S is still zero for column C. For column C (using the number of rainfall days) the positive skill over climatology is 0.67 and for column D (using rainfall calendar date averages), it is then 0.63. The average of the two comparisons is 0.65. Using the same method as above, real-time forecasts were made for the 1972–73 and 1973–74 Los Angeles rain seasons and gave, respectively, 3.01 and 4.76 times as much rain for the predicted rainier halves as for the predicted drier halves of the 27-d cycles. The 1973–74 forecast was monitored by the Los Angeles office of the National Weather Service.

Rainfall may occasionally be scant within an entire 27-d interval. This may occur if the 54-d cyclic component is then more effective or if storms are blocked by a strong ridge of high pressure which sometimes forms over the western states and persists for a few weeks. When the southern part of the landward extension of the East Pacific high is over Los Angeles, as the cell moves northward during the drier half, the wind direction is from the east since the high circulates in a clockwise sense. Then the East Pacific high over Los Angeles can help create the Santa Ana wind condition (foehns) and higher temperatures from compressional effects as air flows downhill toward the coast. Rain washes pollutants out of the atmosphere and cold fronts associated with storms do not favour formation of low-temperature inversion layers. For the 1972–73 rain season figures obtained from the Los Angeles County Air Pollution Control District show that, on average, the ozone level was 43.5% higher and the nitrogen oxides 11.3% higher during the predicted drier halves of the five principal 27-d rainfall cycles.

Our analysis indicates that the phase of the 27-d cycle usually remains the same for most or all of a particular rain season, and that the phase changes usually occur be-

Column B gives rainier-to-drier half ratio for predicted intervals. Column C gives same ratio using climatology statistics consisting of total number of days of rainfall on each calendar date for 1919–1973. Column D gives the ratio using statistics of average amount of rainfall on each calendar date from 1919–1973. Column E gives day of year (1 to 365 or 366) on which each forecast began. 0 in column E indicates no forecast made.

tween rain seasons. Some very small effects on rainfall are associated with both the full moon and new moon which occur every 14.7 d (refs 4, 9). This particular lunar phase effect would give roughly equal rainfall contributions (14.7 d apart) to the drier and rainier halves of the Los Angeles 27-d rain cycle and is probably not related to it. The Sun and solar sector structure also produce atmospheric effects¹⁰. But our studies of the rainfall cycle's phase indicate that it is not simply driven by either solar or lunar processes. If the periodicity is of solar or lunar origin, then its phase must be determined by another mechanism.

Just off the northwest coast of the United States, confluence (narrow, strong jet stream) is associated with the Gulf of Alaska surface low surmounting the eastern cell of the Pacific high¹¹. These unusual circumstances provide very good conditions for high zonal index so storm tracks can stay north of Southern California a long time. We now consider the possibility that the spectral peaks in Fig. 2 arise from resonances of the atmospheric subsystem regulating the weather, including the Gulf low and the Pacific high, in the Eastern Pacific region at northern hemispheric mid-latitudes. The spectra suggest the possibility that this resonance is excited by time dependent processes with energy at frequencies closer to higher harmonics than to the fundamental of the subsystem and closer to some harmonics than to others. Since atmospheric systems are "deformable", we might expect a somewhat different fundamental and a different set of harmonics in years when the atmospheric conditions were different. The differences in the spectra in curves 4 (1936-1971) and 5 (1900-1935) may be the result of a long term change in the state of the atmosphere. Thus, Conover¹², citing work by Petterssen¹³, states that the global trend of rising temperatures diminished after about 1937-1940. He relates changes in temperature trends to changes in the mean atmospheric state of meridional flow relative to zonal circulation.

Concentrating solutes with membranes containing carriers

We have developed membranes which can rapidly concentrate a specific solute against its concentration gradient. These membranes depend on mobile carriers and are examples of *in vitro* systems which exhibit characteristics of biological transport. When combined with the 'liquid surfactant membrane' geometry, they offer a method for wide classes of large scale separations. We show here how our specific results provide a blueprint for designing additional membrane systems.

The membranes operating in our laboratories at present are summarised in Table 1. These membranes depend on mobile carriers which react rapidly and selectively with the solutes being transported. Two mechanisms are involved. In the first (Fig. 1), the flux of the protons which supply the energy is in the opposite direction to the flux of the solute being moved against its gradient, resulting in counter-transport^{1,2}. The second mechanism is analogous to that shown in Fig. 1, except that both the protons and the solute being separated combine with the carrier on the same side of the membrane. As a result, the two fluxes are in the same direction, resulting in co-transport. Moreover, because all of these membranes are chemically well defined, they can be understood on a molecular basis, and the diffusion and chemical reaction responsible for their operation can therefore be studied in detail³.

Additional membrane systems can be developed in a straightforward manner. An organic solution containing a complexing agent for the relevant solute must be chosen. This solution and the complexing agent will become the membrane material and the mobile carrier, respectively. The degree of complex formation must vary strongly with pH, and both carrier and complex must be soluble in the membrane solution but insoluble in aqueous acid and base. One then runs two extractions sequentially. For example, a solution of 500 parts per million (p.p.m.) mercuric ion in 2 M NaCl and 1 M HCl is mixed with a membrane solution of 10% trioctylamine in *o*-xylene. The mercuric ion and the protons complex with the amine and dissolve in the organic phase. When this organic phase is

* All these systems have been checked by double extraction and in a membrane geometry.

extracted with 500 p.p.m. mercuric ion in 2 M NaCl and 0.3 M NaOH, the mercury concentration of the basic solution is increased. The two extractions produce a net transfer of

material, and therefore this chemical system provides a potential separation process. As a thin layer dividing two aqueous solutions, it will function as a membrane capable of concentrating a specific solute.

The real interest in these membranes, however, arises when they are converted into the geometry of synthetic vesicles or 'liquid surfactant membranes'⁴. This geometry consists of small drops of solution coated with the liquid membrane and suspended in a solution of different concentration. Because these bubbles have such a large area per volume, diffusion in and out of the bubbles is much faster than is possible with classical membrane geometries. Separation has been achieved on an industrial scale, but the selectivity of these separations was controlled by solubility differences alone.

Bubbles coated with membranes containing carriers, like those in Table 1, have three advantages over those based on solubility alone: they can concentrate as well as separate a given solute; they have inherently much greater selectivity; and they are applicable to a much wider variety of chemical systems. These advantages accrue from the specific chemical reactions between carrier and solute. Because these reactions include a much wider spectrum of effects than solubilities do, a much greater variety of phenomena are possible.

An example of the properties of the bubbles coated with membranes containing carriers is shown in Fig. 2. In this experiment, 10 ml of 0.1 M NaOH was prepared. The membranes were made of light mineral oil containing 4 weight % trioctylamine and 1 weight % sorbitol monooleate. These bubbles were added, whilst stirring, to 100 ml of solution containing 100 p.p.m. chromium at pH = 1.6. The concentration of chromium in the bubbles rose from an initial value of zero, past the concentration in the bulk solution, to a value of 900 p.p.m. after 4 min, and the chromium concentration in the bulk solution decreased correspondingly. The very rapid uptake with very little amine provides an intriguing alternative to conventional ion exchange.

We have shown here how the membrane mechanisms postulated⁵ in biology can be generalised to produce a variety of chemically well defined analogues to living membranes. Although we have reported only data for inorganic ions, these principles can be extended to other solutes, including antibiotics, detergents, and amino acids. When these transport systems are used in conjunction with the technology developed for liquid surfactant membranes, separations of considerable

practical potential are obtained.

Removal of ozone from the atmosphere by soil and vegetation

OZONE is the principal constituent of the photochemical smog that plagues many cities in the United States. Produced by the action of sunlight on the hydrocarbons and oxides of nitrogen emitted by vehicles and industry, concentrations of ozone greater than 25×10^{11} molecules cm^{-3} (1×10^{11} molecules $\text{cm}^{-3} = 0.4$ parts per hundred million $= 8 \mu\text{g m}^{-3}$), used as evidence of photochemical smog¹, have been observed in Los Angeles for more than two decades². Because of lower air temperatures, less sunshine and fewer vehicles, photochemical pollution was considered unlikely to occur in Western Europe but concentrations indicative of photochemical smog have now been reported from Germany³, the Netherlands^{4,5} and southern England^{6,7} on calm, sunny days. High concentrations of ozone cause respiratory difficulties in humans⁸ and damage many plants⁹ including crops¹⁰.

The Earth's surface acts as a sink for ozone produced in the upper atmosphere¹¹. The rate of removal of ozone varies with the surface: water, snow, grass, and a juniper bush remove it increasingly quickly^{12,13}. Since soil bare of vegetation also removes ozone from the atmosphere at rates similar to those previously observed over land¹⁴, the role of vegetation is not clear. Laboratory studies with individual plants have indicated that vegetation removes ozone from the air when the stomata are open¹⁵⁻¹⁷.

We have examined the role of vegetation and soil as sinks for atmospheric ozone in the field. For this we constructed a mathematical simulator of ozone removal by vegetation and soil. In the laboratory, the rate at which bean plants removed ozone from the air corresponded to a resistance to ozone removal about the same as that encountered by water leaving the leaves through the stomatal pores¹⁵. After taking into account the different rates of diffusion of water vapour and ozone, we obtained similar results for young maize plants. The resistances to ozone removal and evaporation were 271 and 270 s cm^{-1} respectively in the dark and only 3 and 4 s cm^{-1} respectively in the light. This similarity of resistance to ozone removal and transpiration of water implies that at the cell walls beneath the stomata, where the air is saturated with water, the concentration of ozone must be essentially zero. Thus ventilation and

stomata alone control ozone removal by a leaf. This inference has suggested that simulators of evaporation can be modified to calculate the ozone removal by vegetation¹⁸.

Our simulator of ozone removal is based on a simulator of evaporation^{19,20}. The salient features of the simulator of evaporation are its conception of evaporation as an energy exchange process, the predominance of vertical exchange between the canopy and air above over horizontal exchange, the division of the canopy of leaves into strata, the use of stomatal and atmospheric resistances to evaporation, and the use of boundary conditions of temperature and humidity above and below the leaf canopy. The exchange of ozone can be compared with the flow of a direct electrical current through a series of resistances. This clarifies the concept of exchange and simplifies the algebra. The maize canopy may be depicted with eight strata of leaves and a basal stratum of stems.

The flux of ozone into each stratum of leaves or into the soil is opposed by vertical resistances to exchange from one stratum to the next, and within each stratum the exchange is opposed by the resistances of the boundary layer and stomata. The vertical transfer resistances and boundary layer resistances are the same as encountered by sensible heat or vapour transfer, and the stomatal resistance only needs to be modified for the different rates of diffusion of ozone and water vapour. Using the rules of electrical currents, as shown elsewhere¹⁸⁻²¹, we can relate the products of the fluxes of ozone into the leaves and soil, and the resistance to these fluxes to the differences in concentration of ozone at the canopy top and near the ground. Thus, the simulator enables us to calculate the ozone removal by soil and vegetation from the concentration of ozone at the top and bottom of the canopy if we know the vertical transfer resistances, the resistances to removal by the stomata and leaf boundary layer, and the leaf area distribution.

We first calculated the evaporation from measurements of temperature and humidity above a canopy of known leaf area per stratum, the temperature and humidity near the ground, the radiation absorbed by the canopy, the stomatal

Fig. 1 Relation between ozone concentration and logarithm of height within and above a maize field. The concentration is presented as a percentage of that at 350 cm: 11×10^{11} mol cm^{-3} in 1971 and 31×10^{11} mol cm^{-3} in 1972. The dashed line indicates the height of the maize and the bars denote twice the standard error of the mean of four observations in 1971 and eight observations in 1972. Ozone concentrations were measured with a model 724-2 Mast (Mast Development Company, Davenport, Iowa) ozone meter fitted with a trap for sulphur dioxide. The meter was suspended from a vertical tower, so that it could be rapidly moved between pre-set heights from 2.5 to 350 cm above the soil. Each observation at a particular height was quickly compared with the concentration at 350 cm. Concentrations at seven heights were usually measured during a 20 to 30 min sampling period.

Table 1 Calculated removal of ozone by maize and soil

	August 9, 1971					August 22, 1972

§ Layer 2.5 cm thick above soil.

and boundary layer resistances within each stratum and the vertical diffusivities within the canopy. We then compared the evaporation calculated by the simulator with actual observations of evaporation from a portion of the crop growing in a pair of weighing lysimeters.

Our test site was a 1 hectare field of a cultivar of *Zea mays* at the Lockwood Farm, Hamden, Connecticut. The maize was planted in mid-May to give a final population of 75,000 or 93,000 plants per hectare and a leaf area index (LAI) of 4.3 and 3.0 in 1971 and 1972 respectively. On August 9, 1971 and August 22, 1972, both clear sunny days with abundant ozone throughout the afternoon, the ozone concentration, net radiation, temperature, humidity, ventilation, stomatal resistance and evaporation were measured between 1330h and 1930h Eastern Standard Time (EST).

August 9, 1971 was slightly warmer and drier than August 22, 1972, and the combination of days and diurnal changes provided a range of weather conditions. The concentration of ozone varied markedly between the two days but not during a particular sampling period. The mean ozone concentration at 350 cm was 11×10^{11} molecules cm^{-3} in 1971 compared with 31×10^{11} molecules cm^{-3} in 1972; the decrease in concentration of ozone with height (Fig. 1) indicated that ozone was diffusing downwards into the canopy and soil. The comparison of evaporation from the lysimeters with that calculated from our observations of weather and plant factors for a range of conditions (Fig. 2; data obtainable from authors) showed that our estimates were realistic. We had to adopt the same rules as in ref. 24 to calculate the vertical resistances within the canopy and avoid impossibly rapid evaporation from the soil.

Assured that the vertical, boundary and stomatal resistances to vapour exchange in the different strata were realistic, we used them in the simulator of ozone removal. The simulated profiles of ozone concentration within the leaf canopies were then compared with the actual profiles measured in the field (Fig. 3). The good agreement gave us confidence in the simulator of ozone removal.

The calculated removal of ozone by the foliage plus soil at five times in both 1971 and 1972 is shown in Table 1. The calculated removal by the foliage was markedly affected both by the ozone concentration and by the aperture of the stomata. The flux of ozone into the soil beneath the maize was similar to that measured earlier¹⁴ over bare soil on several days when the ozone concentration was about 12×10^{11} molecules cm^{-3} .

We also calculated the removal of ozone by bare soil

Fig. 2 Comparison of calculated and measured evaporation. To calculate evaporation, the net radiation above the crop was measured continuously with a Beckman and Whitley (San Carlos, California, Model 188-01) net radiometer. The coefficient of extinction of net radiation within the canopy was calculated from the leaf area and the logarithm of net radiation measured at five heights within the canopy with a portable net radiometer (Thorntwaite, Centerton, New Jersey, Model MNR540). The temperature and humidity at the canopy top (225 cm in 1971 and 200 cm in 1972) and at 10 cm above the soil were measured with a ventilated wet-bulb psychrometer (Bendix, Friez Instrument Division, Baltimore, Maryland, Model 566-2). The temperature, humidity, and net radiation within the canopy were measured near the beginning and end of each period. The horizontal wind was observed at four heights above and one height within the canopy with sensitive cup anemometers (Casella, London, Model T16112), and the mean windspeeds for the sampling period were then used to calculate the vertical transport coefficient, or diffusivity, at the canopy top. During each sampling period, the stomatal resistances of the upper and lower leaf surfaces of two leaves per stratum were measured with a ventilated diffusion porometer²². The resistances were measured on two plants growing in one of a pair of lysimeters²³ that measured the evaporation during each period. The lysimeter, ozone meter, and micrometeorological towers were approximately 7 m from the northerly edge and 150 m from the southwestern, leading edge of the field.

for the same concentrations of ozone but assuming that the canopy was not present. For this we used vertical resistances appropriate to bare soil¹⁴. The calculated removal of ozone by the soil had the crop been absent varied from 11 to 17×10^{11} molecules $\text{cm}^{-2} \text{s}^{-1}$ (Table 1). By difference, the additional removal of ozone by the foliage over that removed by bare soil was 0 to 23×10^{11} molecules $\text{cm}^{-2} \text{s}^{-1}$. Thus, even this more conservative estimate of the contribution of the foliage indicated that the crop increased the removal of ozone from the atmosphere while the stomata were open, but the decrease in ventilation by the crop decreased the flux of ozone into the soil and hence decreased the net impact of the crop. On the two occasions on August, 9 1971 when the calculation implied that the removal by bare soil would have been greater than by the crop and soil together, the stomata were closed, thus the foliage was removing little ozone, but it was slowing the ventilation and thereby slowing the removal of ozone by the soil.

The combined resistance of the soil and 2.5 cm air layer above it varied from 0.5 to 5 s cm^{-1} (Table 1), and was similar to the 2 s cm^{-1} observed previously¹⁴. Since the resistance of soil increases with moisture¹⁴, the variation in the resistance from 1971 to 1972 may simply reflect the greater amount of water in the soil in 1972. During the 7 d before measurement the rainfall was 3.5 mm in 1971 compared with 23.9 mm in 1972. Alternatively the differences may also reflect our inability to specify accurately the diffusivity in the air near the ground²⁴.

The calculations of ozone removal by the soil and maize are, however, reasonable, and clearly indicate that both soil and vegetation removed ozone when the stomata were open. It is known that in some species ozone closes the stomata^{25,26}, but our measurement of stomatal resistance were similar to those we had reported previously for maize^{24,27}, indicating that the maize stomata were not closed by the ozone. Clearly, however, closure of stomata or leaf injury by ozone will reduce the removal of ozone by vegetation.

Finally we determined whether a forest also cleanses ozone from the air. We chose a mixed hardwood and coniferous forest where the trees were about 25 m tall and had a leaf area index of about 3. We measured the concentration of ozone with a portable meter at a height of 0.3 m over a nearby lake and at seven stations within the forest along a 150 m line parallel to the prevailing southwest wind. Since the ozone concentration was similar all over the lake, only one station was established over the lake, 1 m from the shore. The meter was then moved

Fig. 4 Ozone concentrations measured at various distances from the shore of a lake into a forest. Concentrations are related to the 30×10^{11} molecules cm^{-3} at the shore. The bars denote twice the standard error of the mean of five observations between 1330 and 1850 h EST on August 23, 1972.

quickly between the stations, and the concentration observed for 1 to 2 min at each station. The decrease of ozone at stations within the forest (Fig. 4) indicated that the forest was removing ozone from the atmosphere, even when observation were made in the direction of the 450 cm s^{-1} wind.

Soil is a major sink for the carbon monoxide²⁸ and vegetation is an important sink for the sulphur dioxide²⁹ emitted into the atmosphere by man's activity. Since ozone is not emitted directly into the atmosphere, but is generated from other pollutants, a knowledge of its production in the atmosphere is required for a similar evaluation to be made for ozone. Recent estimates^{30,31} indicate an ozone production rate of nearly 10×10^{11} molecules $\text{cm}^{-2} \text{s}^{-1}$ in the lowest 2 km of the atmosphere. Clearly, a rate of removal or destruction of ozone of 6×10^{11} – 34×10^{11} molecules $\text{cm}^{-2} \text{s}^{-1}$ by soil and vegetation together could account fully for this estimated rate of production, and indicates that the soil and vegetation represent primary sinks for photochemically produced ozone.

We thank Timothy D. Buckelew, James E. Farrell, L. Earl Gray, Harley Tomlinson, Philip F. Tomlinson and Kathryn Woglom for assistance with the data collection. How sea snakes may avoid the bends

MARINE snakes and turtles are probably the deepest diving reptiles. Sea snakes dive to maximum depths of at least 40 m with air in the lung¹. Pressure at this depth potentially produces the formation of N₂ bubbles in the blood and other tissues during decompression, yet sea snakes ascend to the surface rapidly and do not seem to be affected by caisson disease. Here I show that N₂ concentrations in the blood and tissues may remain much lower than that in the pulmonary blood because of a large venous shunt and a low but significant permeability of the skin to dissolved gas.

When a snake dives, the pressure in the lung increases, causing N₂ to move into the blood and from there into the tissues, tending toward equilibrium with pulmonary N₂. Because the N₂ concentration in seawater varies insignificantly with depth, diving creates a N₂ gradient between the blood and the seawater, and N₂ is lost at a rate dependent on the magnitude of this gradient and the resistance to diffusion through the skin. N₂ increases in the blood and tissues until the rate of gain from the lung equals the rate of loss through the skin. The N₂ content of the blood when equilibrium is reached is the maximum value that will occur at any particular depth. This value may be roughly estimated from the N₂ pressure in the lung, the diffusion coefficient of the skin, the cardiac output, and the degree of shunting of venous blood past the lung.

Because of the incompletely divided ventricle, shunting of venous blood from the right atrium to the systemic circuit (right to left shunt) may occur. Right to left shunting may also occur, in effect, if the blood in the pulmonary circuit does not fully equilibrate with the lung gas. For this discussion, it does not matter where right to left shunting occurs, in the heart or the lung. It is useful only to partition the systemic outflow into two fractions: one with the gas concentration equal to the venous return (that is, the shunted blood) and one having a gas concentration equal to that in the lung (that is, the effective pulmonary flow).

The net N₂ flow from the lung in ml min⁻¹ (\dot{V}_L) depends on the effective pulmonary blood flow in ml min⁻¹ (\dot{Q}_L) and the difference in N₂ concentration in ml ml⁻¹ between the blood functionally entering the lung (C_{sv}) and leaving it (C_{lv}).

$$\dot{V}_L = \dot{Q}_L (C_{lv} - C_{sv}) \quad (1)$$

The N₂ loss from the surfaces of the snake (\dot{V}_s) may be considered to depend on the diffusion coefficient D , and the gradient between the blood (C_{sa}) and the seawater. For this discussion, D is defined as the rate of gas movement through the entire gas permeable surface of a snake in response to a gradient of 1 atmosphere absolute (ATA) between the seawater and the arterial blood (ml min⁻¹ ATA⁻¹). Thus D varies with the size of the snake. This simplification permits conversion of the observed rate of extrapulmonary O₂ uptake to an estimate of N₂ diffusion out. A N₂ content (STPD) of 1 ml ml⁻¹ in blood is equivalent to a N₂ pressure of about 70 ATA at 30° C (ref. 2) and the N₂ pressure in seawater is about 0.78 ATA.

$$\dot{V}_s = D(70C_{sa} - 0.78) \quad (2)$$

At equilibrium, $\dot{V}_L = \dot{V}_s$.

$$\dot{Q}_L (C_{lv} - C_{sv}) = D(70C_{sa} - 0.78) \quad (3)$$

The N₂ concentration in the venous systemic blood (C_{sv}) is related to the systemic cardiac output (\dot{Q}_a), the rate of N₂ loss (\dot{V}_s), and the concentration in the arterial systemic blood (C_{sa}). Any heterogeneity in C_{sa} due to unequal distribution of shunted blood to the left and right aortic arches is ignored but, as will become evident, this does not greatly affect the results.

$$C_{sv} = C_{sa} - (\dot{V}_s / \dot{Q}_a) \quad (4)$$

Substituting (2) into (4)

$$C_{sv} = C_{sa} - [D(70C_{sa} - 0.78)] / \dot{Q}_a \quad (5)$$

Substituting (5) into (3) and solving for C_{sa}

$$C_{sa} = (0.78D(\dot{Q}_a - \dot{Q}_L) + \dot{Q}_a \dot{Q}_L C_{lv}) / (70D(\dot{Q}_a - \dot{Q}_L) + \dot{Q}_a \dot{Q}_L) \quad (6)$$

At equilibrium C_{sa} is maximal and is the highest N₂ concentration in the blood except in the pulmonary vein. The internal tissues may eventually equilibrate with the arterial blood so C_{sa} is important in determining the potential for N₂ bubble formation. Although C_{lv} may be much greater than C_{sa} , the small amount of N₂ in the pulmonary vein may be quickly diluted in the systemic circuit during decompression. C_{sa} increases with higher \dot{Q}_L or lower D . If there is no N₂ loss ($D = 0$) or if no shunting occurs ($\dot{Q}_a = \dot{Q}_L$), the N₂ pressure in the blood and tissues approaches that in the lung ($C_{sa} = C_{lv}$).

It is possible to estimate equilibrium C_{sa} in a hypothetical 100 g sea snake diving to various depths (Fig. 1). Systemic cardiac output (\dot{Q}_a), estimated with the Fick principle from the arterial-venous O₂ difference of *Hydrophis belcheri* during spontaneous diving (R.S.S., and M. E. D. Webster, unpublished) and the rates of pulmonary and extrapulmonary O₂ uptake of a 100 g *Pelamis platurus*³, is assumed to be constant at 6 ml min⁻¹. The rate of cutaneous O₂ uptake is related directly to the O₂ gradient across the skin of *Pelamis platurus* (J. B. Graham, unpublished) and *Pseudemys scripta*⁴ which indicates that gas exchange is limited by diffusion rather than blood flow. At 30° C the O₂ uptake through the skin of *Pelamis platurus* is about 0.13 ml min⁻¹ with an O₂ gradient of one ATA (ref. 3). Because N₂ diffuses through tissue at about 55% of the rate of O₂ (ref. 5), the N₂ diffusion coefficient (D) becomes 0.07 ml min⁻¹ ATA⁻¹. Assuming 1 ml of blood holds 0.014 ml N₂ ATA⁻¹ (ref. 2), C_{lv} is calculated from the pulmonary N₂ pressure at depth. As not all of the O₂ absorbed from the lung is replaced by CO₂, N₂ accounts for about 95% of the lung volume after long breath holding (R. S. S., and M. E. D. Webster, unpublished).

The overall venous contribution to systemic cardiac output has been estimated to average 66% of the total in two sea snake species; about 80% of the blood in the left aortic arch and 50% of that in the right arch effectively bypasses the lung (R. S. S., and M. E. D. Webster, unpublished). If the blood N₂ threshold for bubble formation for cats (3.3 ATA at sea level)⁶ applies in sea snakes, decompression sickness cannot occur at depths less than about 50 m (Fig. 1). If no shunting occurred, the critical limit in the arterial blood would be reached at only 25 m,

Fig. 1 Maximum blood N_2 concentration (C_{sa}) in a hypothetical 100 g sea snake when the rate of N_2 gain from the lung equals the rate of loss to the seawater at various depths. The effective shunting of venous blood past the lung is indicated as the fraction of systemic cardiac output. — — — Near the threshold for N_2 bubble formation in the blood of cats at sea level⁶.

a depth which produces caisson disease in humans following repeated breath-hold dives⁷. Lung volumes in diving *Pelamis platurus* (~ 9.5% of the body volume)⁸ and green turtles, *Chelonia mydas*, (~ 12% (ref. 9)) indicate that enough N_2 is available to saturate the tissues to dangerous levels. Equilibrium C_{sa} may never be reached, however, if voluntary dives are terminated before enough N_2 can be removed from the lung. Right to left shunting and cutaneous N_2 loss nevertheless decrease the risk of bubble formation during repeated or deep diving.

Because some degree of shunting may occur in other reptiles, it seems that sea snakes were preadapted for avoiding caisson disease when they invaded the ocean. Right to left shunting seems to be higher in sea snakes than in other reptiles breathing normally (R. S. S., and M. E. D. Webster, unpublished). Most reptiles show little or no intraventricular shunting when O_2 remains in the lung¹⁰. It is perhaps significant that all other measurements come from terrestrial or fresh water species which would not normally encounter great depths. Shunting should be measured in marine turtles which may dive to 290 m (ref. 11). Cutaneous gas exchange has been demonstrated in several species of turtles⁴. Berkson¹² observed that the arterial N_2 concentration in *Chelonia mydas* stabilises at values which are considerably less than those predicted by the pulmonary N_2 concentration at various ambient pressures. This occurred at pressures less than that required to compress the pulmonary gas into the rigid nonabsorptive air passages. Berkson suggested that shunting might account for this but did not consider cutaneous N_2 loss.

The mechanism described here may not be the only adaptation of sea snakes for avoiding caisson disease. It is possible that the poorly vascularised sacculus portion of the lung limits N_2 absorption in the manner proposed for the tracheal and bronchial dead spaces in diving turtles¹² and mammals¹³. If this occurs in sea snakes, however, O_2 uptake would necessarily be inhibited and one would wonder why they dive with a considerable amount of air in the lung. Moreover, horizontal or vertical swimming might be difficult if the gas were retained only in the posterior sacculus portion of the lung.

This report resulted from the Ashmore Reefs expedition of the R/V Alpha Helix supported by the National Science Foundation

under grants to the Scripps Institution of Oceanography, and was prepared during the tenure of an Australian Research Grants Committee Grant. I thank F. N. White for commenting on the manuscript.

On Allen's suggestion for long-distance translocation in phloem of plants

N. S. ALLEN has made a film of the streaming of cytoplasm in *Nitella*, in which she used laser light through chloroplast-free 'windows' in the walls of the giant alga cell to take a cine film under Nomarski optics. This film shows that the cytoplasm, which seems to flow steadily and spirally along the axis of the cell, contains undulating filaments that apparently provide the motive force for streaming. It is postulated¹ that endoplasmic filaments undulate in a sinusoidal fashion and thereby drive the cytoplasm. There is some supporting evidence that these filaments are branches originating from microfilament bundles which in turn are normally anchored and parallel to the fixed chloroplast rows. The waves passing along the semi-free microfilament branches cause them to act somewhat like beating flagella in other organisms.

Allen has suggested that some similar systems may be operating in sieve tubes in the phloem of plants. Two possible ways in which this might occur are given in Fig. 1. In Fig. 1a the microfilament material (m.f.m.) is shown attached to the plasma membrane and lateral walls of the sieve tubes. The swishing of these microfilaments would presumably continue through the sieve tube pores in sieve plates. In Fig. 1b (closer to the Allen proposal for *Nitella*) some fibrils persist as axial bundles from plate to plate, through the pores and lumina, though some may be anchored to the plates near the pores. Attached to these by one end only are loose branches of microfilaments which, it is postulated, can swish sinusoidally and hence propel sucrose solution linearly along channels through the lumen and sieve plate pores. We have carefully considered these suggestions in the light of the cine film study of D. R. Lee, D. S. F., and J. W. Costerton. Either model should produce an apparent mass flow with the profile of an activated diffusion², but model b fits more closely the evidence of the cine film study. Neither model will, however, account for a bimodal type of translocation whereby small pulses of sucrose precede the mass flow mode^{3,4}. We therefore propose a slight modification of Allen's hypothesis shown in Fig. 2, whereby the axial fibrils are thought to have flagella-like branches, but also to have hollow

Fig. 1 Sieve tube and plate illustrating mass flow activated by swishing microfilament material (m.f.m.) attached *a*, to the sieve tube walls; *b*, to axial fibrils.

centres so that a small amount of sucrose can be moved ahead of the mass flow by a kind of microperistaltic movement. Such a model overcomes a difficulty in the proposals of D. S. F. whereby many parallel bundles 20–60 nm diameter would be required to operate in phase and in parallel through sieve plate pores. This new model agrees much more closely with the electron micrographs of Robidoux *et al.*⁵ and also with the freeze-etching work of Johnson⁶. It does require the existence of some transcellular material which an increasing number of investigators now believe to exist. But this axially oriented material could not be in the form of membrane-bound tubules of 5–0.5 μm in diameter, at least in *Heracleum*, for these would be clearly visible in living sieve tubes using Nomarski optics nor would a mass flow mode then be possible⁷.

The reasonable nature of these proposals can be demonstrated when Allen's hypothesis¹ is applied to calculate the probable order of magnitude of the energy dissipation in sieve tubes of *Heracleum*. We assume that the motive force causing flow operates throughout the length of the sieve tubes, that is, along the channels in the lumina and across the sieve-plate pores and we can write¹ the expression for the propulsive force per wavelength of a single filament as

$$F_p = 2\pi^2 b^2 V_m (C_N - C_T) / \lambda$$

where V_m is the measured velocity, about $3 \times 10^{-2} \text{ cm s}^{-1}$ (ref. 5); b is the amplitude of the vibration, about $2.3 \times 10^{-6} \text{ cm}$; λ is the wavelength, about $1.1 \times 10^{-5} \text{ cm}$.

The parameters b and λ are not based on *Heracleum*, for good micrographs by freeze-etching technique are not yet available for this plant. But Johnson⁶ has published electron micrographs of the sieve elements of *Nymphaeoides* using freeze-etching techniques. One of these (his Fig. 2) seems to show wave-like structures of repeating pattern suggestive of helical forms. Johnson has interpreted these as filaments, for they are more regular in pattern than the ramifications left between ice crystals and they appear as an array of dots. Tentatively assuming that these waveforms are the vestiges of filaments and that the pattern in *Nymphaeoides* would be reasonably similar to that in *Heracleum*, we have obtained the mean measurements given above.

C_N and C_T are the surface coefficients of resistance acting, respectively, normal and parallel to the axis of the tube. The

values of C_N and C_T for small fibrils can be calculated from the equations

$$C_N = 2C_T \text{ and } C_T = 2\pi \nu / (0.5 + \ln(r/\lambda))$$

where ν , the viscosity, is taken as 2×10^{-2} poise (20% sucrose at 20°C) and r the radius of the filaments is taken as $5 \times 10^{-7} \text{ cm}$ (ref. 5). The numerical values of C_N and C_T are then 0.26 and 0.13 poise, respectively.

Hence $F_p = 1.7 \times 10^{-8}$ dyne per wavelength. The energy dissipation for mass flow will be $F_p \times V_m = 0.5 \times 10^{-9}$ erg per s per wavelength in a single filament. But in one sieve tube there are between 5×10^4 and 5×10^5 filaments in the cross section³ and 6.7×10^4 wavelengths per cm of filament. Hence in 1 cm of sieve tube the energy dissipation would be expected to be in the range 1.7 to 0.17 erg s⁻¹. These values are more conveniently expressed in terms of the rate of consumption of sucrose. For this we assume the number of individual sieve tubes per cm² of sieve tube cross section to be 3×10^5 (ref. 5) and take a value of 4×10^3 calorie per g of sucrose metabolised. Hence, for mass flow alone, the expected rate lies between 1.1×10^{-2} and $1.1 \times 10^{-3} \text{ g sucrose h}^{-1} \text{ cm}^{-2}$ which corresponds to only 1/9,000 to 1/90,000 of the sucrose carried by specific mass transfer, based on sieve tube cross section alone.

Of course, allowance must be made for the pulse flow moiety which seems also to be present. If such a pulse flow travelled by a microperistaltic process as suggested by D. S. F., then the number of transcellular fibrils conducting by this mode need only be perhaps 1/20 of the number previously calculated³ when it was envisaged that all the fibrils were potentially tubular in nature. In other words, we can consider that any one axial tubular fibril complex has at least 20 swishing filament tail units operating around it. Thus the sucrose consumption by this mode, and additional to that required for mass flow, would be about $2.3 \times 10^{-3} \text{ g h}^{-1} \text{ cm}^{-2}$.

Hence we conclude that the mechanisms operating either by undulating filaments alone or by filaments accompanying a

Fig. 2 Diagram of sieve tube and plate illustrating a bimodal system ('activated' mass flow + pulsatory flow) in which the m.f.m. are anchored to axial fibrillar bundles capable of microperistaltic action. *a*, Sieve tube; *b*, individual axial fibril with attached filaments (m.f.m. helices with branches in sinusoidal movement anchored to axial bundle).

microperistaltic moiety in the supporting fibrils are both energetically feasible and seem to be at least an order of magnitude lower than one using microperistalsis in 60-nm diameter tubules alone.

The strength of Allen's suggestion to us is that it provides a motive force through the lumen and sieve plate which assists rather than impedes flow past filamentous material, without invoking large membrane-bound tubules for which there is much less evidence than for transcellular fibrils or bundles of filaments. We hope that other workers in the field will be alerted to see whether further experimental evidence can be found to support it in other plants or to test it. Meanwhile it could be a very important concept in unravelling the problem of the mechanism of long distance sugar translocation in plants.

Effect of vasopressin on the isolated human collecting duct

THE study of human kidney function has been largely indirect, based on clearance studies and interpretation of data from more direct approaches on other animal species. Extrapolation from one species to another, however, is not always justified and the need for accurate information on human kidney function is still great. Obviously, several ethical and practical factors severely limit the use of direct studies (such as micropuncture) on the human kidney.

If some portion of an intact human kidney was isolated *in vitro*, however, renal tubular transport could be studied directly. We have had the opportunity to carry out such a study which has involved isolation and microperfusion of human kidney tubules.

The kidney was from a male foetus 5.5 months old, which was aborted through hysterotomy. The indication for abortion was a D₁ trisomy¹ as diagnosed by karyotype analysis of cultured amniotic cells. The congenital defects included agenesis of olfactory lobes, pulmonary artery stenosis, ventricular septal defects and a single umbilical artery. The kidneys appeared normal in all respects.

The experimental procedure for the renal study was as follows. After removal of the left kidney, one slice was cut and immersed in chilled Ringer's solution. The slice was teased with small forceps and needles under a dissecting microscope². The tubules in the cortex were hard to separate. Eventually, a few fragments could be isolated from the medullary region and were identified as collecting ducts. One of them, after transfer to a special incubation chamber was successfully pump perfused using techniques previously described³. The bathing solution was a Ringer bicarbonate buffer with 5.5 mM glucose pH 7.4, gassed with a mixture of 95% O₂ and 5% CO₂ (ref. 2). The luminal fluid was a phosphate buffer containing 60 mM NaCl (125 mOsmol

kg⁻¹ water), to which ¹²⁵I-iothalamate was added as a volume marker³. This enabled accurate computation of the perfusion rate. Osmotic water permeability was calculated as previously described³. Perfusion was initiated within 90 min after hysterotomy. The length of the tubule exposed to the bathing medium was 400 µm.

The osmotic water permeability after 80 min incubation was 2.48 µl cm⁻² osmol⁻¹ min⁻¹. After the addition of vasopressin (2.13 mU ml⁻¹) to the medium bathing the tubule it rose to 11.98 µl cm⁻² osmol⁻¹ min⁻¹. The values are of the same order of magnitude as those found in the isolated collecting tubule of the rabbit in the presence and absence of vasopressin³. The data are not strictly comparable, however, as the rabbit collecting tubules were obtained from the cortex and the nephron segment in the present study is from the medulla.

During the first hour of perfusion, the epithelial cells appeared cuboidal with barely visible intercellular spaces. The outer diameter of the tubule was 43 µm and the inner diameter 21 µm. After the addition of vasopressin, striking morphological changes occurred. These included cell swelling, vacuolisation and conspicuous dilatation of intercellular spaces (Fig. 1). These changes accompanied the increase in osmotic water permeability and indicated that outward net water movement occurs through intercellular channels as well as through the cell membranes. The structural changes are quite similar to those previously found in the isolated rabbit collecting tubule⁴.

Additional experiments are needed to substantiate the results of the present study. Nevertheless, our first data

Fig. 1 Micrograph of living perfused human collecting duct. Focal plane at the central axis on the right and at apical surface of the cells on the left. *a*, Before vasopressin; *b*, after vasopressin ($\times 520$).

suggest that in man the collecting tubule receptors for vasopressin are well developed during prenatal life. It is likely therefore that the failure of the infant to excrete a concentrated urine cannot be attributed to a lack of end-organ responsiveness to antidiuretic hormone, as previously proposed³.

The inadequate renal concentrating ability in the newborn presumably reflects a poorly developed osmotic gradient in the medulla⁶.

The present study provides the first reported evidence that the function of the human nephron can be directly evaluated with the help of *in vitro* microperfusion techniques. Further work with similar material or with fresh, undamaged portions of surgically removed kidneys will be required to gain direct insight into renal tubular transport mechanisms in man.

Mutagenicity of chromates in bacteria and its relevance to chromate carcinogenesis

THERE is abundant experimental evidence that certain chromium compounds are carcinogenic in animals^{1,2}. There are also epidemiological data which suggest that chromium compounds are carcinogenic in man^{3,4}. Calcium chromate especially, produces epithelial lung tumours both by intra-bronchial implantation¹ and sarcomata by intramuscular administration to rats³. In epidemiological studies Bidstrup and Case⁴ reported a significantly high lung cancer mortality in men who worked in chromate-producing factories, and concluded that the most likely explanation of this increased risk was due to an occupational carcinogen.

The mechanism of chromate carcinogenicity is not understood. But considerable evidence exists which suggests that chemical carcinogens are also mutagens although the converse is not necessarily true⁵. We have, therefore, tested the hypothesis that some chromium compounds, including a known carcinogen, are mutagenic. We have used a simple bacteriological spot-test mutagenicity assay⁶ which has convincingly demonstrated that simple hexavalent chromium salts of Na, K and Ca are indeed mutagenic under conditions where related heavy metal salts show no mutagenic activity. There is no evidence, however, that the highly soluble chromates such as Na and K used in this study are carcinogenic to experimental animals (ref. 7 and L. S. Levy, unpublished data), nor are there reports that they cause cancer in man.

The organisms used in this study were: *Escherichia coli* B/r WP2; WP2uvrA; WP2exrA, which differ in their sensitivity to mutability by ultraviolet and ionising irradiation and a variety of alkylating and arylalkylating agents. All

strains require tryptophan for growth due to an *ochre* mutation in the *trpE* locus⁸.

E. coli K12(λ) CA165 (containing *SupB* (ref. 1) was used in conjunction with bacteriophage T4 *ochre* 427 for characterising the WP2 mutants obtained after chromate treatment⁹.

E. coli WP2 strains were grown overnight in nutrient broth at 37° C and diluted 1:50 in M9 medium containing 0.4% (w/v) glucose and 10 μg ml⁻¹ L-tryptophan. Cells were collected by filtration during mid-logarithmic phase, washed in M9 salts and resuspended at 5 × 10⁸ cells ml⁻¹ in M9 salts and kept on ice until used. For mutagenicity assays by the spot-test method 5 × 10⁷ bacteria were spread on agar plates containing M9 medium, 0.4% (w/v) casamino-acids and 1 μg ml⁻¹ L-tryptophan. Test compounds (Analar where available, otherwise General Purpose Reagent Grade, obtained from Hopkin and Williams, Romford, Essex, England) were dissolved in deionised water, filter-sterilised, and 5 μl applied to the centre of each plate. Pre-existing revertants were assayed on agar plates containing M9 medium, and never exceeded 2-3 colonies per five replicate plates. Plates were incubated at 37° C and the maximum yield of mutants (that is, revertants to tryptophan prototrophy) was obtained 4-5 d after plating.

Table 1 shows the results of such an assay using WP2 and three doses of Na₂CrO₄, K₂CrO₄, and CaCrO₄ respectively. Chromate-induced mutant colonies grew more slowly than the larger spontaneous colonies and at the higher doses a central zone of growth inhibition was visible. It is clear from the data presented in Table 1 that all three chromates were equally effective in inducing statistically significant increases (of the order of threefold) in the yield of prototrophic revertants over control levels. The values obtained are of course minimum estimates of the mutant yield since in this method of screening lethality cannot be assessed accurately.

Table 1 Reversion of *E. coli* WP2 (try⁻) to prototrophy after exposure to chromates*

Dose of compound, (μmol per plate)	Revertants per plate (mean of three plates ± s.d.)					
	Na ₂ CrO ₄	P†	K ₂ CrO ₄	P	CaCrO ₄	P
Control	37 ± 10		37 ± 10		37 ± 10	
0.05	125 ± 8	< 0.001	114 ± 16	< 0.01	133 ± 26	< 0.01
0.10	105 ± 10	< 0.01	125 ± 7	< 0.001	99 ± 40	< 0.1
0.20	55 ± 6	< 0.1	127 ± 17	< 0.01	113 ± 34	< 0.05

* Spot-test method.

† P refers to probability in *t* test.

In order to confirm the results obtained using the spot-test method we performed a number of experiments in which bacteria in suspension were treated with Na₂CrO₄, after which the chromate was removed and mutation and lethality then assayed simultaneously (Fig. 1). In both *E. coli* WP2 and WP2uvrA the yield of induced revertants increased linearly with increasing chromate concentration, and there was no significant difference in mutability between the two strains. *E. coli* WP2uvrA was slightly more sensitive to the cytotoxic effect of Na₂CrO₄ than was WP2 (which is wild type with respect to excision repair), the 1/*e* doses being 2 mg ml⁻¹ and 2.7 mg ml⁻¹ respectively.

We obtained negative results with soluble salts of tungsten and molybdenum (the two metals closest to chromium in the periodic table) and also with a soluble trivalent chromium compound, Cr₂SO₄·K₂SO₄·2H₂O. Salts of zinc, cadmium and mercury were also tested and found to be inactive. From the present data, therefore, it seems that of the metals tested, only hexavalent chromium is mutagenic in this system, of which CaCrO₄ alone has been shown to be carcinogenic *in vivo*^{1,2}.

Fig. 1 Dose against survival and mutation of *E. coli* WP2 and *E. coli* WP2uvrA following treatment with Na₂CrO₄ in suspension culture. Bacteria were grown to mid-logarithmic phase (2×10^8 ml⁻¹) in M9 medium containing $10 \mu\text{g ml}^{-1}$ L-tryptophan and collected by filtration and washed in M9 salts. Washed cells were resuspended in M9 salts containing 10 mM Mg^{2+} and 1 mM Ca^{2+} and treated with graded doses of Na₂CrO₄ for 2 h at 37° C. The treated bacteria were washed free of chromate by three cycles of centrifugation in ice-cold M9 salts and resuspended in M9 salts. For assay of viable counts, triplicate 0.1 ml samples at appropriate dilution were plated. Reversion to tryptophan independence was assayed by plating quintuplicate 0.2 ml samples of undiluted bacteria (5×10^7 ml⁻¹) per plate. The plating medium for both viable-count and reversion assays contained 1.5% agar in M9 medium, 0.4% casamino acids, and $1 \mu\text{g ml}^{-1}$ L-tryptophan. Viable counts were scored after 18 h at 37° C, and the full yield of revertants was scored after 4 d at 37° C. Pre-existing revertants were assayed on M9 medium plates. The frequency of induced mutations was calculated according to the formula of Sedgwick and Bridges¹⁵. Each point represents the mean number of colonies of three plates (viable counts) and five plates (mutation frequency). ●, WP2; △, WP2uvrA.

The absence of either the *exrA* repair pathway ('error-prone') or the *uvrA* repair pathway ('excision-repair') did not significantly modify the mutagenic response to chromate (Fig. 1 and Table 2) in this test system. We therefore conclude that chromates fall into that class of mutagens exemplified by hydroxylamine¹⁰, bisulphate¹¹ and ethyl methanesulphonate (EMS) (ref. 14 and E. M. Tarmy, personal communication) which exert their effect by directly modifying DNA bases in such a way that base-pair errors arise at subsequent cell divisions. They do not fall into the second category of mutagens, such as methyl methanesulphonate¹², ultraviolet irradiation¹³, 7-bromomethylbenz[a]anthracene⁹ and nitroquinoline-*N*-oxide¹⁴, whose mutagenicity can be drastically modified or even abolished by the presence or absence of DNA repair processes.

Table 2 Mutagenicity of K₂CrO₄ in three DNA-repair strains of *E. coli* WP2*

Bacterial strain	Revertants per plate (mean of three plates ± s.d.)			<i>P</i>
	Control	Treated (0.05 μmol K ₂ CrO ₄ per plate)		
WP2	Exp. (a) 37 ± 10	114 ± 16		< 0.01
	Exp. (b) 28 ± 6	155 ± 20		< 0.001
WP2 _{exrA}	Exp. (a) 22 ± 8	65 ± 5		< 0.001
	Exp. (b) 30 ± 9	70 ± 6		< 0.001
WP2 _{uvrA}	1 Exp. 37 ± 7	74 ± 11		< 0.02

* Spot-test method.

We investigated the specificity of the postulated base-pairing error by determining the ratio of true revertants (that is, structural reversions at the *trpE* locus) to *ochre*-suppressor-containing revertants in a population of chromate-induced mutants (Table 3). We found that in the chromate-treated group, 98% of revertants contained *ochre* suppressors compared with 45% in the untreated (spontaneous) group. The reversion from tryptophan auxotrophy to prototrophy in this system involves mutation at an *ochre* triplet, UAA (containing only AT base-pairs in DNA)*.

Table 3 Characterisation of *E. coli* WP2 revertants obtained after treatment with K₂CrO₄

	No. of revertants lysed by T4 <i>ochre</i> 427	No. of revertants not lysed by T4 <i>ochre</i> 427	Total no. of revertants tested
Spontaneous revertants (untreated)	9	11	20
Induced revertants (chromate treated)	98	2	100

100 revertant colonies arising from a K₂CrO₄-treated plate, and 20 revertant colonies from an untreated plate, were purified by repeated subculture on minimal medium agar, and overnight nutrient broth cultures were prepared. A lysate of bacteriophage T4 *ochre* 427 was prepared by growth in and lysis of *E. coli* K 12 CA 165 in M9 containing 1% lactose and 0.4% casamino acids. This lysate, after centrifugation, contained less than 0.04% revertant bacteriophage when assayed on *E. coli* WP2. 0.2 ml of each purified revertant culture was mixed with 0.1 ml T4 *ochre* 427 (2×10^4 PFU ml⁻¹) in 0.6% agar at 46° C and poured on to plates containing nutrient agar supplemented with 1% glucose. *E. coli* WP2 which is not lysed by T4 *ochre* 427, and *E. coli* CA 165 which is, were used as controls¹⁶.

Since the treated population contained only 2% true reversions (of which some may well be spontaneous in origin), it is highly likely that chromate does not modify AT base-pairs, but specifically attacks GC base-pairs, causing GC to AT transitions at a subsequent round of DNA replication. In this respect, as well as in its mutagenicity in *Exr*⁻ bacteria, chromate closely resembles EMS, hydroxylamine and bisulphite, which have also been shown to specifically induced GC at AT transitions^{10,11}.

Transepithelial potential difference in toad urinary bladder is not due to ionic diffusion

KOEFOED-JOHNSEN and Ussing proposed¹ that the transepithelial potential difference (PD) in frog skin was due to the sum of two diffusion potentials, one at the outside border due to sodium, and one at the inside due to potassium. Others have shown somewhat similar results in toad urinary bladder^{2,3}. Although there is evidence to support the notion that such a mechanism cannot account for the entire PD⁴⁻⁶, the hypothesis is still favoured by many investigators.

The hypothesis might be true if when the sodium pump is inhibited or stimulated, the same changes in PD occur

Fig. 1 Response of control bladders to ionic changes. The transepithelial potential is plotted against the mucosal sodium or serosal potassium (— — —) concentration. ●, ○, Experiments performed with chloride as the major anion; ▲, △, Experiments done in sulphate media. In each case progressive Na for K substitutions were made in the appropriate medium and the resulting PD measured. Vertical lines indicate \pm s.e.m.

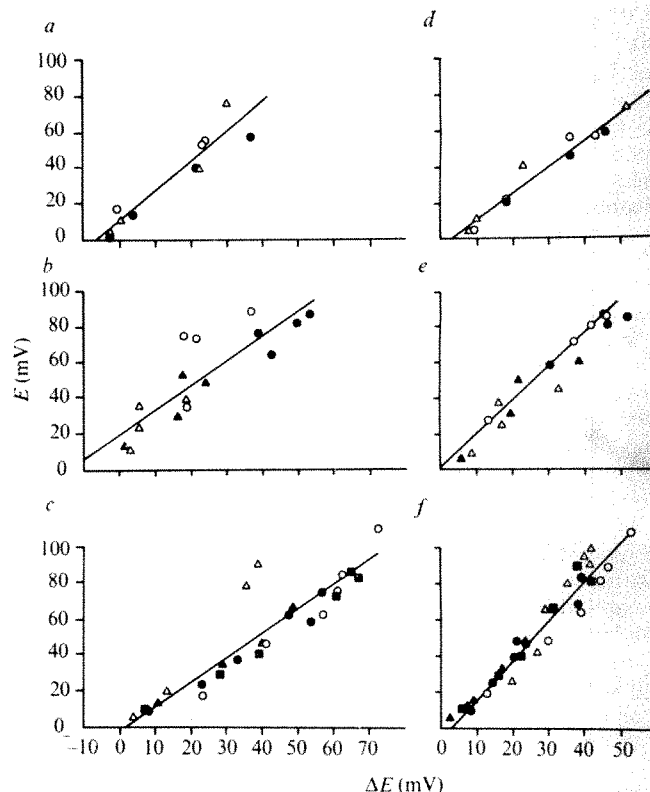

Fig. 2 Effect of inhibition of the transepithelial potential on the response to changes in ionic constituents. Each panel represents a series of studies on several bladders, and studies on a single bladder are shown for each panel as like symbols. *a* and *d* show the result of mucosal (*a*) and serosal (*d*) ionic changes in ouabain experiments. *b* and *e* show mucosal (*b*) and serosal (*e*) ionic changes in experiments in which the temperature was changed. *c* and *f* show mucosal (*c*) and serosal (*f*) ionic changes. *a*, $y = 1.65 (\pm 0.17) x + 10.3 (\pm 3.2)$, $r = 0.95$; *b*, in amiloride experiments, $y = 1.40 (\pm 0.21) x + 20.1 (\pm 5.8)$, $r = 0.88$; *c*, $y = 1.35 (\pm 0.12) x - 1.59 (\pm 5.16)$, $r = 0.91$; *d*, $y = 1.50 (\pm 0.10) x - 5.5 (\pm 2.9)$, $r = 0.98$; *e*, $y = 1.79 (\pm 0.13) x + 0.90 (\pm 4.1)$, $r = 0.97$; *f*, $y = 2.19 (\pm 0.11) x - 5.86 (\pm 3.28)$, $r = 0.97$.

when medium Na or K concentrations are changed as are seen in the control state, even though cell Na and K may have reached a new steady state value. That is, for example, whatever the cell K concentration, a tenfold change in serosal medium K would result in a more or less instantaneous tenfold change in the concentration ratio $K_{\text{cell}}/K_{\text{medium}}$, and the PD, a logarithmic function of the concentration ratio, should decrease by the same absolute amount.

Bladders were dissected from Colombian toads, (*Bufo marinus*), and none were used whose PD was less than 50 mV. The standard Ringer solution used contained (mmol l⁻¹): NaCl, 109; CaCl₂, 0.9; NaHCO₃, 2.4; KCl, 2.5; glucose, 5.5, and was stirred by means of a bubble lift with room air. When sulphate was used as the anion, the solution contained (mmol l⁻¹): Na₂SO₄, 55; K₂SO₄, 1.25; CaSO₄, 0.9; NaHCO₃, 2.4; glucose, 60. When step-wise changes in Na and K concentrations (carried out by K-for-Na substitutions) in the mucosal or serosal medium were made, results were similar to those previously described for this tissue^{2,3}, and were consistent with the interpretation that the mucosal barrier is more permeable to Na than to K, while the opposite is true for the serosal barrier (Fig. 1). Note also that there are only small differences between the results with Cl and those with SO₄²⁻ as the major anion. In all cases, the PD chosen was that seen 2 min after the previous solution was removed; each time a change was made, the chamber was washed three times with the new solution.

When the PD was reduced in seven experiments to 3 ± 1 mV with ouabain (10^{-3} M), however, the decrease in potential following reduction of mucosal Na to 2.4 mM was only 0.9 ± 1.1 mV, and that following the increase of serosal K to 111.5 was 2.3 ± 0.3 mV. Furthermore, when the ambient temperature was reduced to 5°C in two experiments (by means of circulation around the water-jacketed chamber of water from a constant temperature circulator), thus decreasing the PD to 0 and 4 mV, the changes in PD after reduction of mucosal Na to 2.4 mM were 0 and 0.5 mV, and the change after an increase in serosal K to 111.5 was 0 in both cases.

We next brought about a graded reduction in transepithelial PD by (1) progressive increases in the concentration of ouabain (added to the serosal solution only) from 10^{-5} to 10^{-3} M, (2) graded changes in the ambient temperature, and (3) progressive increases in the concentration of amiloride (added to the mucosal solution only, in concentrations ranging from 10^{-7} to 10^{-5} M).

Figure 2 shows the results plotted as ΔE , the change in potential after a solution change, against E , the PD obtained with Ringer on both sides just before the change. Note that essentially the same results were obtained with all inhibitors, and with either mucosal or serosal substitutions. Four further experiments with ouabain and two with amiloride were performed using SO_4^{2-} as the anion; equally strong correlation was found, with $r=0.98$ and 0.93 , respectively. Furthermore, if mucosal sodium was replaced by choline instead of potassium, identical results were obtained in two experiments with ouabain. None of these

Fig. 3 Effect of stimulation of the transepithelial potential on the response to changes in serosal potassium. Data are plotted as in Fig. 2. The four rather low PD values are from two bladders whose PD decreased late in the experiment. In each bladder (shown by like symbols), serosal K was changed from 2.5 to 111.5 before and after the addition of vasopressin (25 mU ml^{-1}) to the serosal side. After the PD reached a new value, Ringer solution (with or without ADH) was replaced in the medium. $y = 1.96 (\pm 0.12) \times -15.5 (\pm 5.7) r = 0.96$.

Table 1 Transepithelial resistance

	Ouabain	Amiloride	Temperature change
Control	2305 ± 304	1493 ± 232	2270 ± 120
Experimental	2293 ± 322	2107 ± 231	3400 ± 209
n	5	4	5

Resistance (given in ohm cm^2) was measured either as the quotient of the open-circuit PD and the short-circuit current, or as $\Delta E/\Delta I$ when a 50 mV voltage step was applied for 20 s. These two techniques give identical results. In each case the experimental resistance shown is that measured at the highest concentration of ouabain or amiloride, or at the lowest temperature, usually 5° or 10°C , and all resistances are given as means \pm s.e.m.

procedures resulted in a decrease in transepithelial resistance (Table 1), thus excluding the possibility that the observations could be due to a progressive decrease in tissue resistance as the baseline PD falls with inhibition of the Na pump. Finally, in experiments in which the transepithelial PD was stimulated with anti-diuretic hormone (ADH), the results of serosal K-Na substitution were identical with those seen with inhibition (Fig. 3).

Since these results are not compatible with the diffusion potential hypothesis, one explanation might be that the permeability characteristics of the mucosal and serosal barriers are in some way determined by pump activity, so that when the pump changes, the permselectivity changes. This requires, according to the results in Figs 2 and 3, however, that at every level of pump activity both mucosal and serosal permselectivity change *pari passu* with the pump. Furthermore, the procedures chosen for pump inhibition and stimulation are quite different in their sites and mechanisms of action, and the fact that nevertheless, both mucosal and serosal characteristics were affected in a similar manner make it unlikely that the resting potential in this and presumably similar epithelia is due to Nernst-like permeability barriers.

The obvious alternative is that the PD is due to the operation of a charge-separating or electrogenic pump, and that the apparent permselectivities deduced from changes in ionic constituents of the media in control preparations depend on the effects of the various ions on the pump itself. Since its characteristics cannot be rigorously defined by these experiments, however, further speculation seems unwarranted.

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, '**Molecular Biology Comes of Age**' looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'**Molecular Biology Comes of Age**' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of '**Molecular Biology Comes of Age**' are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

synaptic vesicles had a high content of acetylcholine (ACh)¹⁻³ and were ideal carriers of 'packets' of ACh released at the synapse, a necessary requirement for the quantal theory of transmission⁴.

Two hypotheses try to explain how the transmitter leaves the cells. One considers that the vesicles, having migrated to strategic presynaptic sites, fuse with the presynaptic plasma membrane and discharge their contents directly into the synaptic cleft⁵. Some electron microscope pictures of the vertebrate neuromuscular junction were interpreted as confirming such liberation of ACh by exocytosis⁶. According to the second hypothesis the ACh of the synaptic vesicles is released into the surrounding axoplasm before crossing the synaptic membrane.

So far, problems of transmitter storage and liberation have been approached mainly by anatomical and biochemical methods. We thought that a physiological approach was possible, taking advantage of the observation that ACh inside the vesicles is protected against the hydrolysing effect of acetylcholinesterase (AChE)^{1,3}, but that ACh in the cytoplasm would be rapidly hydrolysed by AChE.

By artificially introducing AChE into the presynaptic neurone in sufficient quantity to reach the presynaptic terminal, we were able to provide conclusive evidence that synaptic activity in the presence of intracellularly injected AChE is no longer possible. From the evidence presented here we assume that for ACh to act as a transmitter, it must be present free in the axoplasm (eventually released from synaptic vesicles) where it can be broken down by AChE.

In the buccal ganglion of *Aplysia*, two easily identifiable cholinergic interneurons make inhibitory synaptic connections with a number of postsynaptic cells situated close to each other in the same ganglion^{7,8}. After suitable dissection and attaching of the buccal ganglion in an experimental chamber constantly perfused with seawater, one interneurone (injected interneurone) was penetrated with a micropipette filled with purified 5% solution of electric eel AChE in seawater. (Identical results were obtained using AChE from Sigma (type V) or Worthington (type ECHP).) The purity of the Sigma preparation at least can be considered as very high, as when injected in the rabbit only the specific immune serum anti-AChE was found⁹. The injection was performed by an air pressure system similar to that used in a previous study¹⁰. The quantity of solution injected was not known. But, experiments made towards the end of the present study using AChE dissolved in tritiated water enabled the calculation of the intracellularly injected quantity as being about 1% of the volume of the cell soma. The propagation of the enzyme to the presynaptic site was followed with both light and electron microscopy, using an improved version of Koelle's histochemical method¹¹.

The injecting micropipette was also a microelectrode. The postsynaptic potential (PSP) produced by direct stimulation of the interneurone was recorded in one chosen postsynaptic neurone impaled with a double barrelled KCl-filled microelectrode. In some experiments, the second interneurone afferent to the same postsynaptic cell was also impaled (test interneurone) and the synaptic activity monitored. The postsynaptic potentials caused by direct stimulation of the injected and test interneurons were compared throughout the experiment to eliminate possible changes in the properties of the postsynaptic neurone during the relatively long experiments, especially the effect of changes of the membrane potential and of the intracellular ionic concentrations on the amplitude of the synaptic response. During measurement of the PSPs the membrane potential of the postsynaptic neurone was adjusted to -80 mV at which level the IPSP was reversed to a depolarising potential of several mV in amplitude which was more convenient for the experimental analysis.

Fig. 1 Spike responses to direct stimulation of the AChE injected interneurone (upper traces) and the corresponding inverted IPSP in the postsynaptic cell at -80 mV membrane potential (lower trace). Control was taken 30 min after injection. At 2 h 20 min the depression of the PSPs was complete.

All experiments were performed at room temperature (20° – 22° C). After injection of AChE no significant change was observed in the respective amplitudes of the injected or test interneurone PSPs for about 2–2.5 h; then, in about 20 min or less, the PSP produced by stimulation of the injected interneurone decreased progressively and finally completely disappeared (Fig. 1). The amplitude of the test interneurone PSP remained within the normal range. The minimal time course of the depression of the PSP was identical whether the injected interneurone was previously firing at a high rate or whether its activity was completely abolished by hyperpolarisation.

In experiments in which presumably lesser amounts of AChE were injected, the injected neurone PSP decreased also but the changes in amplitude started after a longer time interval. Within 1 or 2 h an amplitude was reached which then remained relatively constant with respect to the test PSP or decreased slowly until the end of the experiment, that is for about 4 more hours.

It does not seem that the depression of synaptic transmission is caused by some modification in the size or con-

Fig. 2 Spike responses to direct stimulation of the injected and test interneurons and the corresponding inverted IPSPs in the postsynaptic cell at -80 mV. Traces of test spikes are omitted in the two lower recordings. Control was taken 30 min after AChE injection. The quantity of AChE was not sufficient to block the PSP due to the injected interneurone. The PSP corresponding to the test interneurone was not significantly changed.

duction of the spike, as the amplitude as well as the resting potential remained very much the same throughout the experiment (Fig. 2). Also the synaptic delay, in so far as it was detectable, remained constant. In addition the distance between the soma and the ending is short enough so that synaptic efficacy can be affected by modifying the somatic membrane potential by applied current (T. Shimahara and L. Tauc, unpublished) which leads one to suppose that membrane properties changing in the axonal part of the neurone would be detectable in the soma. Also the decrease of the PSP was continuous, without steps, indicating that there was no blocking of presynaptic spike on axonal branchings.

The injection of seawater alone or with addition of inactivated AChE in the same experimental conditions did not produce any change of synaptic efficacy in the injected cell. Contamination of our AChE preparation with proteases or any other enzymes seems highly unlikely. But, since no analysis was done, contamination causing the effect on synaptic activity observed here was ruled out by performing control experiments. Intracellular injection of mixtures of various proteases, especially trypsin and chymotrypsin, produced at higher concentrations marked modifications of the membrane potential and conductance, and of the spike of the injected cell. With concentrations too small to cause these changes in the properties of membranes no effect was detected on the level of the synapse.

Histochemical studies showed that AChE effectively propagates into the axon and in the axonal branchings in the neuropile (Fig. 3). The electron microscope (EM) pictures give additional evidence that AChE had reached the preterminal region of the injected axon. The black precipitate masks subcellular structures on the ending, but in some EM photographs, synaptic vesicles can be observed in spite of the abolition of transmission.

The distance from the soma of the studied terminal can

be estimated as <1 mm; the speed of propagation of the injected AChE was then about $200\text{--}300\text{ }\mu\text{m h}^{-1}$, comparable with the slow rate of progression of AChE in the vagus nerve¹².

Unless there exists a quite improbable action of sub-products of ACh hydrolysis, or an unknown effect of AChE on molecules other than ACh, our results indicate that before its liberation, ACh has to be present in the axoplasm where it is exposed to the hydrolysing action of AChE. ACh is in the axoplasm because it is synthesised there; and possibly it comes from the synaptic vesicles. Vesicular ACh does not seem to be released directly into the synaptic cleft, a conclusion that can be deduced from the result observed here that the minimal time of AChE effect on active and inactive synapses is very much the same. Indeed, if ACh stored in the vesicles was released directly into the synaptic cleft a contrary result would be expected, because the vesicular ACh is protected against AChE action, and thus would remain available for longer. This theory is strengthened by the presence of quite considerable ACh stores in *Aplysia* cholinergic synapses, demonstrated by using hemicholinium-3, which need intensive and prolonged stimulation to become exhausted¹³, and also by a rather slow loss of vesicular ACh observed *in vitro*¹³ and *in vivo* when axoplasmic ACh of *Torpedo* was drained by intensive stimulation¹⁴.

It is interesting to note that the presence of axoplasmic releasable ACh demonstrated here in a form which can be attacked by AChE could also be explained by the existence of two pools of ACh, free and bound, the free pool containing the releasable ACh, a hypothesis which has been proposed by Dunant *et al.*¹⁵.

We thank Dr Taxi for facilities and discussions, and Dr T. Shimahara for his participation in the early part of this work. This work was partially supported by an ATP grant from CNRS and a grant from INSERM.

Y chromosome effect on adult testis size

DURING the development of mammals with X and Y chromosomes the Y chromosome brings about the differentiation of the gonad primordia into testes¹. But apart from carrying the genetic determinants of maleness, little is known about its genetic constitution. In man, the gene for hairy tips to the ears shows Y linkage in at least some pedigrees². In mice there is evidence for a Y-linked histocompatibility locus^{3,4}, and for effects of the Y chromosome on the frequency of spermatozoa with abnormal heads⁵. Here we show that the size of the testes of adult mice is affected by factors on the Y chromosome.

Male mice of the CBA/FaCam strain are fully fertile, but have testes which are much smaller (90–110 mg) than those of males of most other strains^{6,7}. The differences remain significant when variation in bodyweight has been corrected for by regression analysis⁸. Small gonads have also been found in the J and Kw sublines of CBA^{7,9}. A comparison of CBA/FaCam mice with those of the A/Cam, SF/Cam and Peru strains showed that, after correction for variation in bodyweight, 87% of the observed variation was due to differences between the strains, 6% was due to litter effects and 7% to other environmental sources of variation. Reciprocal cross fostering of newborn mice between the CBA and Peru strains did not affect the size of the testes of adults of either genotype, showing that postnatal maternal effects were absent. A diallele analysis of simultaneous crosses between these three strains revealed significant general ($F_{6,321} = 383$) and specific ($F_{6,321} = 83$) combining abilities. There were significant differences between reciprocal crosses ($F_{6,321} = 48$). In all the crosses (see Table 1) F_1 males with CBA fathers had smaller testes than males from the reciprocal cross which had CBA mothers. This pattern of results is that expected for Y-linked factors but not for X-linked factors, or for direct maternal effects. Mice were bred from 18 further crosses between the CBA and SF strains. Table 2 summarises observations on the parental strains, reciprocal F_1 , F_2 and backcrosses, and on four F_3 and two F_4 crosses. All 11 stocks with Y chromosomes from the CBA strain had lower mean testis weights than the 11 stocks with a Y chromosome from the SF strain. Eleven A \times CBA hybrid generations showed the same pattern of results. Table 2 indicates that the average effect of a CBA Y chromosome was to depress mean testis weight by 31 mg. More sophisticated maximum likelihood analyses⁸, however, estimated the Y effect as 24 mg, which represented 41% of the CBA-SF strain difference of 58 mg. In the F_4 generation the two lines which differed in Y chromosomes differed in mean testis weight by 24 mg. All genetic models which omitted a Y effect were much poorer fits than ones which included such an effect. The remainder of the strain difference was due to several (more than two) autosomal factors and to interactions between sex-chromosomes and autosomes.

The testes of CBA mice grew more slowly, at least after birth, than those of mice of other genotypes. The lower weight of testes from CBA mice was detectable well before puberty, and seemed to be due to differences in the length of the semi-

niferous tubules rather than in their diameter, or in the quantity of interstitial tissue present. CBA mice are fully fertile (personal observation and ref. 5) and had morphologically normal sperm⁵. Thus they were very different from C57BL/10J mice⁷, even though adult males of both strains had small testes. The C57 phenotype, which only developed after puberty, was not due to Y-linked genes⁷. The post-pubertal fall in testis weight was secondary to deficiencies in the production of androgens by interstitial cells. Spermatogenesis and fertility were consequently affected in C57 mice, as was the development of sex differences in several target organs of androgenic steroids¹⁰. Unlike the C57 mice, the CBA mice showed no signs of androgen deficiency and had normal spermatogenesis⁹ and a clear sex difference in kidney weight. CBA males were found to have smaller seminal vesicles than those of SF mice, but the inheritance of this difference was free from Y-linked effects⁸,

Table 2 The mean testis weights of CBA, SF and hybrid mice arranged in descending order

Stock	Y chromosome	Mean (mg)	s.e.	Sample size
F_1 (C) (S)	SF	165	2.0	66
BC (S) (CS)	SF	158	3.9	25
F_3 (SC.CS) (SC.CS)	SF	155	4.6	14
F_2 (SC) (CS)	SF	151	2.9	37
F_4 High	SF	146	4.3	9
BC (C) (CS)	SF	144	1.5	70
F_3 (CS.SC) (SC.CS)	SF	142	2.2	33
Strain SF (S) (S)	SF	140	1.9	75
BC (SC) (S)	SF	140	3.6	38
BC (CS) (S)	SF	138	2.5	55
F_2 (CS) (CS)	SF	136	2.8	62
BC (S) (SC)	CBA	132	3.6	38
F_1 (S) (C)	CBA	128	2.0	76
F_3 (CS.SC) (CS.SC)	CBA	125	6.7	8
F_4 Low	CBA	122	3.1	13
F_2 (CS) (SC)	CBA	121	3.0	61
BC (C) (SC)	CBA	121	1.8	69
F_3 (SC.CS) (CS.SC)	CBA	118	3.4	31
F_2 (SC) (SC)	CBA	110	2.9	61
BC (CS) (C)	CBA	107	2.0	64
BC (SC) (C)	CBA	101	1.8	68
Strain CBA (C) (C)	CBA	92	1.0	68

All measurements were made on mice aged eight weeks and were corrected to a bodyweight of 21 g by regression analysis. The letters in parentheses refer to the genetic origin of the hybrids. The first set define the female parent used in the cross and the second set define the male parent. Thus F_1 (C) (S) was the F_1 bred by crossing CBA females with SF males, and the F_2 (SC) (CS) mice were bred by crossing F_1 (S) (C) females with males from the reciprocal F_1 (C) (S) cross. The F_4 high mice were [(SC.CS) (CS.SC)] [(CS.SC) (SC.CS)] and the F_4 low mice were [(CS.SC) (SC.CS)] [(SC.CS) (CS.SC)]. BC, Backcross.

and was not causally related to variation in testis weight. Genetic variation affecting the sensitivity of seminal vesicles to testosterone is known^{11,12}.

The synteny of the CBA factors and the Y-linked histocompatibility locus is intriguing as factors concerned with the small testes of C57 mice seem to be linked to the H-2 histocompatibility locus on chromosome 17 (ref. 13).

The Y effect on gonadal development is large enough to be experimentally useful, yet does not produce infertility. Thus CBA mice, and hybrids derived from them, are excellent material for investigation of the function of the Y chromosome and for studies of the regulation of gonadal development¹⁴.

Much of the work described in this paper was carried out in the Department of Genetics, University of Cambridge. We wish to thank Professor J. M. Thoday for his interest and encouragement, and the Medical and Science Research Councils for financial support.

Development and genetic analysis of *bithorax* phenocopies in *Drosophila*

PHENOCOPIES are developmental abnormalities which closely resemble known mutants, and can be induced experimentally¹. Phenocopies of a given mutant can be induced by various physicochemical agents, which share a unique and restricted effective period in development. In some instances it has been shown that the period of sensitivity to the agent coincides in turn with the effective period of the mutant itself^{2,4}. This is of special relevance because it places the phenomenon of the phenocopy in the same causal frame as that of gene action. Some of the morphogenetic mutants of *Drosophila* have been studied in clonal analysis and shown to act cell autonomously^{5,6}. We have investigated whether their phenocopies also result from events taking place at the cellular level.

In the present work phenocopies of mutants of the pseudoallelic *bithorax* system of *Drosophila* have been studied. Phenocopies of the mutant *bithorax*—one of the alleles—have been found following ether^{8,10} and temperature shocks¹¹ to embryos during the first 6 h of development. The genetic basis⁷ and developmental clonal parameters⁸ of these homeotic mutants are known. Our main conclusions are: (1) phenocopies can be induced before the syncytial nuclei reach the cortex; (2) the effect is produced in individual cells which propagate their new state by cell heredity; (3) the genetic constitution of the egg, with respect to some alleles of the *bithorax* system, has no effect on its sensitivity to ether.

Eggs were collected, following a prelaying period, for 0.5 h on a filter paper sprayed with a yeast suspension. At different times after oviposition the filter paper was transferred for 10 min to a 50 cm³ chamber with a saturated ether atmosphere. The adults were scored under the binocular microscope and subsequently mounted in Euparal for microscopic examination.

In wild-type flies the frequency of *bithorax* phenocopies varies with developmental age (Fig. 1). Phenocopies appear in embryos treated less than 30 min after oviposition (before the syncytial nuclei reach the cortex¹²), their frequency increases to a maximum in embryos treated at 2-2.5 h (syncytial blastoderm) and decreases to zero in eggs treated after 5 h (following gastrulation). It is interesting

to note that the embryonic mortality which follows ether treatment is not correlated with the frequency of *bithorax* phenocopies (Fig. 1).

Fig. 1 Frequency of egg mortality (●) and of *bithorax* phenocopies (○) in wild-type individuals following ether treatment at different embryonic stages. The actual number of phenocopies is given in parentheses.

The phenotypes of the different pseudoallelic mutants of the *bithorax* system have been described in detail elsewhere⁷. *Bithorax* (*bx*) transforms the anterior and *post-bithorax* (*pbx*) the posterior metathorax, towards the corresponding regions of the mesothorax. Both regions are transformed in *Ultrabithorax* (*Ubx*) flies. A complete metathorax may appear instead of the normal mesothorax in *Contrabithorax* (*Cbx*) flies. Whereas the first two mutants are recessive and possibly correspond to structural loci, the last two are dominant and have been thought to represent operator mutations affecting the transcription of the entire *bithorax* system⁷.

In standard series of 3-h-old embryos, (experiments 1 and 2, Table 2) phenocopies of the different *bithorax* alleles appear with characteristic frequencies. A sample of 1,048 hemithoraces, corresponding to 524 phenocopy-carrying flies was studied. Phenocopies of *bx* in both dorsal and ventral (sternopleura) metathoracic regions appeared with a frequency of respectively 75% and 27% of the hemithoraces, and are usually the most frequent ones. Phenocopies of *pbx* are more difficult to identify, those with features of clear posterior wing, such as alula, appeared in 2% of the halteres. *Cbx* phenocopies—halter territories instead of wing structures in the mesothorax—were also found, but only in three cases (0.3%).

As previously observed⁸ phenocopies affecting both sides of the same thorax are more frequent than expected on the basis of independent events taking place on each side. This finding could indicate that the phenocopying agent produces some interference with the organisation of the embryo as a whole.

But, several observations suggest that phenocopies occur locally, affecting neighbouring cells in the embryo. Phenocopies are patchy, affecting different and discrete regions of the disk derivatives (see Fig. 2). In 728 hemithoraces, phenocopies embracing structures of both notum and wing represent 34% of the cases, those affecting only notum structures 11% and those affecting only wing structures 47%. In 54 cases (7%) we found independent spots in both notum and wing or in two separated regions of the wing.

Table 1 Frequency of *bithorax* phenocopies in different genotypes

Also, the shape of the phenocopy patches resembles that of mitotic recombination clones of, for example, *bx³/bx³* homozygous cells in a heterozygous *bx³/+* haltere background⁸. Also, phenocopy patches correspond in size to one or more recombination clones of *bx³/bx³* cells initiated in first instar larvae. Finally, the borders separating transformed from nontransformed cells in phenocopies are clear cut, as in recombination clones. All these facts taken together suggest that the process which produces phenocopies acts on cells or groups of neighbouring cells which retain their abnormal determination during subsequent development.

This hypothesis was tested in the following experiment. Eggs of the genetic constitution, *mwh jv/M(3)i⁵⁵* were treated with ether at an age of 3 h and the early second instar larvae (72 h) irradiated with 1,000 r. X rays. Mitotic recombination induced by X rays will give rise to non-Minute cells, homozygous *mwh jv* (two-cell marker mutants), which will overgrow their neighbouring Minute cells and build large marked clones¹³. Among 474 hemithoraces (from 358 flies) with phenocopies we found 38 cases of *mwh jv* clones in the dorsal metathorax in either the haltere or in the transformed wing territories. These clones never included both haltere and phenocopied wing cells. In 22 cases the borders of the clones ran for some way along the separation between transformed and nontransformed cells (Fig. 2). As expected these clones did not cross the compartment borders of the phenocopied wing or those homologous borders in the haltere¹³. These results demonstrate that phenocopied cells maintain in their clones the effects of the phenocopying agent after its removal.

The possible role played by the genetic constitution of the egg upon the frequency of phenocopies was tested in crosses of females heterozygous for *bithorax* mutants and a balancer chromosome (TM1, *Mé*, *sbd*) with wild-type males. In the progeny, flies carrying the mutations and flies carrying the balancer chromosome (internal controls) can be distinguished. As shown in Table 1 flies heterozygous for the recessive alleles *bx³* and *pbx* (experiments 3 and 4) or the doubly heterozygous flies (experiment 5) show similar frequencies of phenocopies to internal controls (TM1) and wild-type flies (experiments 1 and 2). Flies heterozygous for the dominant alleles *Ubx¹* and *Cbx* (experiments 6 and 8) behave in a similar way. However, *Ubx¹³⁰* heterozygous flies (experiment 7) show a much higher frequency of phenocopies than control flies. The extent and types of the phenocopies in flies heterozygous for *bithorax* alleles are similar to those in control individuals, mentioned above, with three exceptions: (1) *Ubx¹³⁰* flies show, together with a higher frequency, a higher expressivity in the transformation than flies of the other genotypes, including *Ubx¹*; (2) *Ubx* flies show *bx* phenocopies in

the haltere (Table 1), but also transformation of part of the mesothoracic haltere territory back into wing (9 out of 92 hemithoraces); (3) in *bx³ pbx/Ubx¹* flies, which are phenotypically *bithorax-postbithorax*, we did not find any transformation of either mesothoracic or metathoracic wing back into haltere.

These results indicate that neither the maternal genotype nor the allelic constitution of the cells, wild-type or heterozygous with respect to *bithorax* (with the exception of *Ubx¹³⁰*), affect the sensitivity of the cells to phenocopies. The possibility of phenocopying *Cbx* wings in wild-type flies, mesothoracic haltere in *Cbx* flies back into wing, but not mesothoracic or metathoracic wings of *bx³ pbx/Ubx¹* flies back into haltere, suggests that wing and haltere developments are not reciprocally reversible.

The gene products of the *bithorax* system are assumed to be active in normal flies in the metathoracic segment, preventing mesothoracic development, and inactive in the mesothorax⁷. Thus, we can suppress, by the action of phenocopying agents, the function of the *bithorax* genes in either the metathorax (*bx* and *pbx* phenocopies) or in the mesothorax (suppression of the *Cbx* phenotype), but we cannot produce a haltere development in flies defective for the *bithorax* genes. If we assume that ether interferes with segmental positional signals in the cortex¹⁴, metathoracic properties would appear in an otherwise mesothoracic segment (leading to *Cbx* phenocopies) or *vice versa* (*bx* and *pbx* phenocopies). This hypothesis is consistent with the fact that phenocopies can be obtained even before the migration of the syncytial nuclei into the cortex (Fig. 1). Thus, it is possible that *bx* and *pbx* phenocopies result from the repression of the *bithorax* system in the metathorax. It is therefore interesting that in heterozygous flies only *Ubx¹³⁰* leads to a higher frequency of phenocopies relative to controls. *Ubx¹³⁰*, a rearranged chromosome with one break point in the *bithorax* locus, could represent an operator-deficient mutant and so heterozygous *Ubx¹³⁰* flies will lack one of the two possible repressor binding sites.

We have seen that *bithorax* phenocopies induced in the blastoderm cells are faithfully transmitted in the progeny of individual cells. But, mitotic recombination in heterozygous cells for structural genes, for example, *bx³/+* haltere cells, induced any time during development, lead to clones of *bx³/bx³* cells which show growth and differentiation properties of the anterior wing⁸. Thus, phenocopies of *bithorax* must consist of a stable inactivation of the entire *bithorax* system, irrespective of the allelic state of their structural genes. This inactivation is reminiscent of the process of determination and indicates that both may take place at the cellular level. We hope that the combined studies of genetic variables and of their phenocopies will throw new light on the underlying mechanism of cell

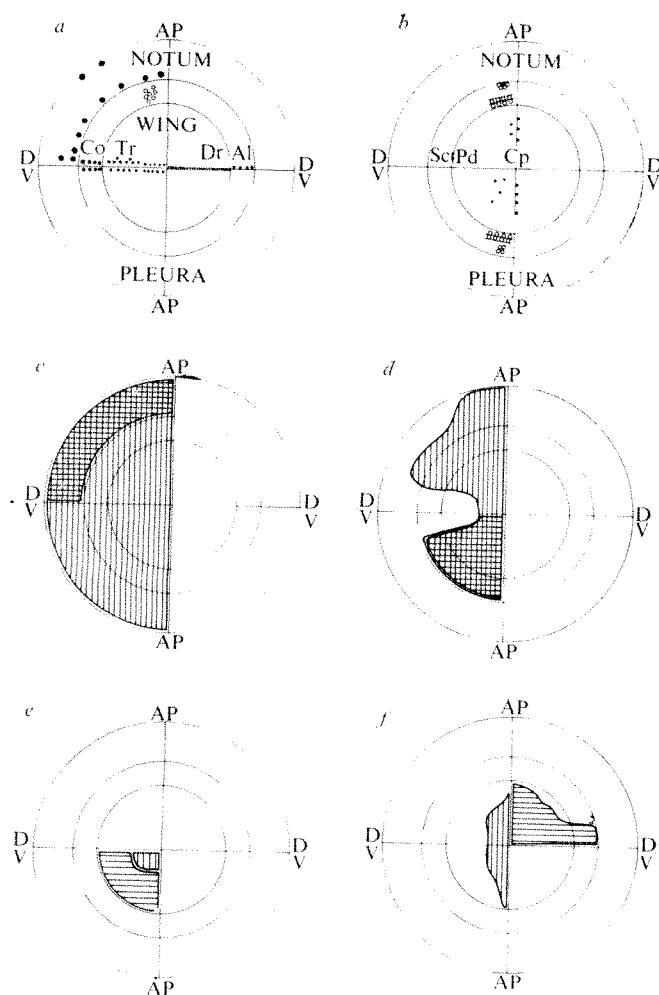

Fig. 2 *a-f*, Schematic representation of the adult dorsal mesothoracic (*a*) and metathoracic (*b*) disk derivatives with their region-characteristic landmarks (●, macrochaetes; ●, microchaetes; ○, sensillae).
